3 We analyzed the sensitivity analysis of the outflow hydrograph from the BREACH model to the
4 main input parameters of the model. The results of the internal friction angle, cohesion and
5 inflow rate to the barrier lake are shown in Fig.S1-3. The outflow hydrograph is more sensitive
6 to the cohesion than to the friction angle, especially when the cohesion value is low. The inflow
7 rate is quite sensitive: higher inflow to the lake will lead to a rapid increase of the flood magnitude
8 and a shortening of the peak of the outflow hydrograph (Fig.S3).
