Received and published: 21 November 2013

I have something to append to my review...

Somewhere (maybe Section 2.2) you should say that the main hypothesis of your work is that the avalanches do not generate a pressure that can break the trees. In fact, you consider small and medium-size avalanches, which presumibily are not able to generate such pressures. Which are the tange of the pressure on the trees (small obstacles), calculated from your model? What do your data tell? Did you find broken trees along the path? Otherwise, obviously, the avalanches would not slow down due to detrainment but because it loose energy in breaking the trees. Bu this is another story...
