

Interactive comment on “Seasonal forecasting of fire over Kalimantan, Indonesia” by A. C. Spessa et al.

Anonymous Referee #1

Received and published: 4 September 2014

In this paper the authors propose a valid method for long-term fire danger assessment using long series observations on burnt area, rainfall and tree cover. It is an interesting study, especially considering the usefulness of the approach in terms of fire management policies. The methodology is clearly explained, the figures and tables are well represented and the conclusions are consistent. I recommend the acceptance with some revisions regarding the general edition and the correspondence between the citations in the text and in the reference section (i.e.: Field et al., 2008; Field et al., 2004; Reid et al., 2012).
