This paper shows results about comparison of different earthquake forecasting models applied to Ryukyu and Kanto regions. The author shows different approaches related to different earthquake forecasting methods: I think that the description of the models is done in an appropriate manner. I appreciate the evaluation with retrospective testing, but some important technical details are missing on this part. I have three general comments about this work:

1) explain better how the Molchan diagram computation was done.

C3372

2) Chapter 5.1: check your conclusions with the results show in the figure 8 and 9. I think that there is a misinterpretation of the results. I suggest to read this work: <https://gji.oxfordjournals.org/content/172/2/715.full>

3) Chapter 5.3 : if you want to talk also about seismic hazard, please show some hazard maps, to check the differences between models and approaches. Or you can delete this part.
