Thanks the Referee for the valuable comments. The author accepted with pleasure all the comments and made the following replies.

Comment 1: In figure 1 I cannot see the river and basin in this study basin. The author can improve the sketch of the watershed.

Reply: The figure will be amended by adding the drainage waterways and sub-basins in the area in the revised manuscript.

Comment 2: In figure 6, comparing model predictions (3-hr lead time) with measured ones, the results by models display significant fluctuations of the hydrographs. Can the author explain more detailed inside?

Reply: The models predict future water-levels by using two input variables: (1) the cumulative rainfall, and (2) the water-level data from an associate site. while the associate water-level data is rather stable, the rainfall data however exhibits fluctuating pattern, as shown in Figure 2 taking Typhoon Trami as an example. As a result, the predicted water-level also displays certain fluctuations. However, the global trend of the predicted hydrograph is compatible with the measured data.
