Abstract

In this paper, we study the impact of lightning and radar reflectivity factor data assimilation on the precipitation VSF (Very Short-term Forecast, 3 hours in this study) for two severe weather events occurred in Italy. The first case refers to a moderate and localised rainfall over central Italy occurred on 16 September 2017. The second case, occurred on 9 and 10 September 2017, was very intense and caused damages in several geographical areas, especially in Livorno (Tuscany) where nine people died.

The first case study was missed by several operational forecasts, including that performed by the model used in this paper, while the Livorno case was partially predicted by operational models.

We use the RAMS@ISAC model (Regional Atmospheric Modelling System at Institute for Atmospheric Sciences and Climate of the Italian National Research Council), whose 3D-Var extension to the assimilation of RADAR reflectivity factor is shown in this paper for the first time.

Results for the two cases show that the assimilation of lightning and radar reflectivity factor, especially when used together, have a significant and positive impact on the precipitation forecast. For specific time intervals, the data assimilation is of practical importance for civil protection purposes because changes a missed forecast of intense precipitation (≥ 40 mm/3h) in a correct one. While there is an improvement of the rainfall VSF thanks to the lightning and radar reflectivity factor data assimilation, its usefulness is partially reduced by the increase of the false alarms, especially when both data area assimilated.

Keywords: data assimilation, lightning, radar reflectivity factor, RAMS@ISAC.

1. Introduction

Initial conditions of numerical weather prediction (NWP) models are a key point for a good forecast (Stensrud and Fritsch, 1994; Alexander et al., 1999). Nowadays limited area models are operational

38 at the kilometric scale (< 5 km) and data assimilation of observations with high spatio-temporal
39 resolution as lightning or radar reflectivity factor¹, is crucial to correctly represent the state of the
40 atmosphere at local scale (Weisman et al., 1997; Weygandt et al., 2008). This is especially important
41 over the sea, where the absence of local observations can misrepresent convection.
42 The assimilation of radar reflectivity factor is useful to improve the weather forecast considering
43 the high spatio-temporal resolution of radar data.
44 First attempts to assimilate radar reflectivity factor are reported in Sun and Crook (1997, 1998), who
45 expanded VDRAS (Variational Doppler Radar Analysis System) to include microphysical retrieval.
46 Following these studies, several systems to assimilate radar observations, both Doppler velocity and
47 reflectivity factor, were developed (Xue et al., 2003, Zhao et al., 2006; Xu et al., 2010). All these
48 studies showed the stability and robustness of assimilating radar observations as well as the
49 improvement of weather forecast.
50 In addition to direct methods, which assimilate the radar reflectivity factor adjusting the
51 hydrometeor contents, there are indirect methods adjusting other variables. In particular, the
52 method of Caumont et al. (2010) assimilates the relative humidity field. It consists of two different
53 steps: a 1D retrieval of relative humidity (pseudo-profile), which depends on the radar reflectivity
54 factor observations, followed by 3D-Var assimilation of the pseudo-profile. This method has the
55 advantage to reduce the computational cost at the kilometric scale.
56 The choice of updating the moisture field directly is motivated by its greater impact on analyses and
57 forecasts in comparison to that of hydrometeor-related quantities (e.g., Fabry and Sun, 2010).
58 Caumont et al. (2010) showed that the method improved the weather prediction of a heavy
59 precipitation event in southern France and of an eight-day long assimilation cycle experiment.
60 The method was applied in other studies (Wattrelot et al., 2014, using AEROME model; Ridal and
61 Dalbom, 2017; using HARMONIE model), or modified using 4D-Var in place of 3D-Var (Ikuta and
62 Honda, 2011; using JNoVa model) showing its capability to improve the weather forecast. The
63 methodology is also used in the operational context (Wattrelot et al., 2014).
64 Lightning is another important source of synoptic data due to its ability to locate precisely the
65 convection with few temporal gaps (Mansell et al., 2007). In the last two decades, there have been
66 attempts to assimilate lightning into meteorological models both at low horizontal resolution, which

¹ Throughout the paper we use the expression radar reflectivity factor, which is the quantity provided by the radar (and expressed in mm^6m^{-3} or dBz) after conversion from the received power. The radar reflectivity factor is different from reflectivity and is obtained in the special case of Rayleigh scattering. Reflectivity is not the quantity that radars usually provide and display on their screens although most of people refer to it.

67 need a cumulus parameterization scheme to simulate convection, and at convection permitting
68 scales.

69 First attempts to assimilate lightning in NWP models were based on relationships between lightning
70 and rainfall rate estimated by microwave sensors on board polar satellites (Alexander et al., 1999;
71 Chang et al., 2001; Jones and Macpherson, 1997; Pessi and Businger, 2009). In this approach, the
72 rainfall rate was computed as a function of the density of lightning observations and then
73 transformed into latent heat, which was assimilated. The results of these studies showed a positive
74 impact of the lightning data assimilation on the forecast up to 24h also for fields at the large scale,
75 as sea-level pressure.

76 The study of Papadopoulos et al. (2005) used lightning to locate convection and the simulated water
77 vapour profile was nudged towards vertical profiles recorded during convective events.

78 Mansell et al. (2007) modified the Kain-Fritsch (Kain and Fritsch, 1993) cumulus convective scheme
79 to force convection when/where flashes are observed while the convective scheme was not
80 activated in the model simulation, demonstrating the potential of lightning to improve the
81 convection forecast. A similar approach was introduced by Giannaros et al. (2016) into WRF showing
82 the positive impact of lightning data assimilation on the precipitation forecast up to 24h for eight
83 convective events occurred over Greece.

84 Fierro et al. (2012) introduced a methodology to assimilate lightning at convection-resolving scales
85 by modifying the water vapour mixing ratio simulated by the WRF according to a function depending
86 on the flash-rate and on the simulated graupel mixing ratio. The water vapour could be assimilated
87 by nudging (Fierro et al., 2012) or 3D-Var (Fierro et al., 2016).

88 Qie et al. (2014), using WRF, adopted the methodology of Fierro et al. (2012) to assimilate ice
89 crystals, graupel and snow, showing promising results for deep convective events in China.

90 Fierro et al. (2015) studied the performance of the Fierro et al. (2012) method for 67 days spanning
91 the 2013 warm season over the CONUS giving a statistically robust estimation of the performance
92 of the method. The computationally inexpensive lightning data assimilation method improved
93 considerably the short-term ($\leq 6h$) precipitation forecast of high impact weather.

94 Lynn et al. (2015) and Lynn (2017) also applied the method of Fierro et al. (2012) to boost the local
95 thermal buoyancy where/when lightning is observed. Results show that lightning data assimilation
96 improved lightning forecast. Importantly, Lynn et al. (2015) offer an approach to address spurious
97 convection (i.e., convection removal), which is a more challenging problem to tackle.

98 Federico et al. (2017a) implemented the methodology of Fierro et al. (2012) in RAMS@ISAC model,
99 showing the systematic and significant improvement of the precipitation forecast at the very short
100 range (3h) for twenty case studies occurred over Italy; the impact of lightning data assimilation for
101 longer time ranges (6h-24h; Federico et al., 2017b) showed considerable impact on the 6h
102 precipitation forecast, with smaller (negligible) effects at 12 h (24 h).

103 In this paper, we study the impact of radar reflectivity factor and lightning data assimilation on the
104 very short term (3h) rainfall prediction for two case studies in Italy. We use the method of Fierro et
105 al. (2012) to assimilate lightning and the method of Caumont et al. (2010) to assimilate the radar
106 reflectivity factor. The case studies occurred in September 2017. The first case, hereafter also
107 referred to as Serano, occurred on 16 September, was characterized by moderate-intense and
108 localized rainfall. The second case, hereafter also referred to as Livorno, occurred on 09-10
109 September, and was characterized by deep convection and very intense precipitation in several
110 parts of Italy. Even if the Livorno case occurred before the Serano case, we reverse the chronological
111 order in the discussion, ordering the event from the less intense to the most intense.

112 The forecast of severe events at the local scale still remains a challenge because of the multitude of
113 physical processes involved over a wide range of scales (Stensrud et al., 2009). The Serano case
114 study, being localized in space, poses challenges in forecasting the exact position and timing of
115 convection initiation; the Livorno event involves the interaction between a high impact storm and
116 the complex orography of Italy, which is difficult to simulate at the local scale. For the above reasons
117 the forecast of both events was challenging, as confirmed by the poor forecast of RAMS@ISAC. The
118 difficulty to forecast timely and accurately the precipitation field is the reason for choosing them as
119 test cases.

120 This paper presents for the first time the assimilation of the total lightning (intra cloud + cloud to
121 ground) and radar reflectivity factor in RAMS@ISAC and shows how the assimilation of the radar
122 reflectivity factor works together with total lightning data assimilation. Also, this paper shows that
123 the precipitation forecast using cloud scale observations over complex terrain can be accurate,
124 contributing to a number of works on the same subject.

125 The paper is organized as follows: Section 2 gives details on the synoptic environment of the case
126 studies showing daily precipitation, lightning and radar observations; Section 3 gives details on the
127 meteorological model, lightning and radar data assimilation; Section 4 shows the results for three
128 very short-term forecast (VSF), one for Serano and two for Livorno; Discussion and conclusions are
129 given in Section 5. This paper has additional material where we discuss: a) how the lightning and

130 radar reflectivity factors data assimilation impact the total water field evolution; b) the sensitivity
131 of the results to the choice of key parameters of lightning data assimilation; c) the sensitivity of the
132 results to two aspects of the radar formulation; d) the sensitivity of the results to two aspects of
133 RAMS@ISAC setting; e) the impact of lightning data assimilation for a well predicted case study.
134 Supplemental material gives also the form of the forward radar operator.

135

136 **2. The case studies**

137 *2.1 The 16 September 2017 (Serano) case study*

138 During the 16 September 2017 Italy was under the influence of a cyclone that developed to the lee
139 of the Alps. The storm crossed Italy from NW to SE leaving light precipitation over most of the
140 peninsula with moderate rainfall over Central Italy. Figure 1 shows the precipitation recorded by
141 the Italian raingauge network on 16 September 2017. Light precipitation (< 5 mm/day) is reported
142 by 1018 raingauges out of the 1666 stations measuring precipitation (≥ 0.2 mm/day) on this day.
143 Fourteen stations over Central Italy recorded more than 50 mm/day. The maximum precipitation
144 was 90 mm/day in Città di Castello (Umbria Region, Figure 1). Because the meteorological radar
145 closest to the maximum precipitation is over mount Serano (Figure 1), hereafter this event will be
146 referred to as Serano.

147 The synoptic condition during the event is shown in Figure 2. At 500 hPa (Figure 2a) a trough,
148 elongated in the SW-NE direction, extends over Western Europe and air masses are advected from
149 SW towards western Alps. The interaction between the airflow and the Alps generates a low
150 pressure to the lee of the Alps over Northern Italy.

151 The analysis at the surface (Figure 2b) shows the meteorological front represented by the equivalent
152 potential temperature gradient between air masses advected over the Mediterranean Sea from NW
153 and air masses advected from the South over the Tyrrhenian Sea. Notable is the feeding of warm
154 unstable air masses towards Central Italy.

155 Infrared satellite images (Figure 3), from 00 UTC on 16 September to 00 UTC on 17 September, show
156 the cold front structure moving slowly from NW to SE. Interestingly, at 00 UTC on 16 September, it
157 is apparent the well-defined cloud system over Central Italy (red circle of Figure 3a), which caused
158 most of the daily precipitation observed between 43.50 and 45.0 N.

159 The well-defined cloud system over Central Italy is also shown in the radar Constant Altitude Plan
160 Position Indicator (CAPPI) at 3 km above sea level at 02 UTC on 16 September (Figure 4). This CAPPI
161 is formed by interpolating all the available data from the federated Italian radar network

162 coordinated by the Department of Civil Protection (twenty-two radars, see Section 3.3 for their
163 positions) and it is also referred to as the national radar composite (hereafter also mosaic). Several
164 convective cells exceeding 35 dBz can be noted over central-northern Italy. Importantly, the cloud
165 system over Central Italy shown by the satellite infrared channel at 00 UTC (Figure 3a) and that of
166 the radar at 02 UTC have similar positions, showing that the cloud system was active for several
167 hours over Central Italy.

168 Figure 5 shows the lightning recorded by the LINET network (Betz et al., 2009) on 16 September
169 2017. More than 105.000 flashes were recorded; most of them occurred in the afternoon and
170 evening, but a secondary maximum occurred in the night, from 00 UTC to 06 UTC. In this phase,
171 more than 3000 flashes were observed over Central Italy.

172

173 *2.2 The 09-10 September 2017 (Livorno) case study*

174 During the days 09 and 10 September 2017, Italy was hit by a severe storm characterised by intense
175 and widespread rainfall over the country. Figure 6a shows the precipitation on 09 September
176 recorded by the Italian raingauge network. Rainfall was intense over the Alps, where the maximum
177 daily precipitation was observed (193 mm/day), and over Liguria, with precipitation of the order of
178 30-50 mm/day. One station over Tuscany reported 90 mm/day, showing that intense precipitation
179 already started over the Region. The storm on 09 September was intense : 20 raingauges reported
180 more than 100 mm/day and 70 raingauges more than 60 mm/day. In most cases, this precipitation
181 occurred in few hours.

182 The following day (see Figure 6b) had higher rainfall. Precipitation occurred mainly over Central
183 Italy, especially over Lazio, and over Northern Italy, in particular the North-East. In Tuscany, the two
184 stations close to the sea, in the Livorno area, recorded about 150 mm/day mostly fallen in the hours
185 between 00 and 06 UTC.

186 Synoptic conditions leading to this storm are shown in Figure 7. At 500 hPa (Figure 7a) a trough
187 extends from Northern Europe towards the Mediterranean. The interaction between the air-masses
188 and Western Alps generated a pressure low to the lee of the Alps, which crossed the whole
189 peninsula from NW to SE. It is noted the divergent flow over Central and Northern Italy favouring
190 upward motions.

191 At the surface, Figure 7b, the equivalent temperature gradient over the western Mediterranean is
192 caused by the contrast between air masses pre-existing over the sea and air masses advected from
193 France towards the Mediterranean. The pressure field at the surface advects air masses from the

194 South over the Tyrrhenian Sea. These warm and humid air masses feed the cyclone during its
195 development.

196 From a synoptic point of view, Livorno and Serano cases are similar and represent two cyclones
197 developing to the lee of the Alps (Buzzi and Tibaldi, 1978). However, the Livorno case is more intense
198 than Serano.

199 The notable intensity of the Livorno case is confirmed by the lightning observations (Figure 8).
200 During the evening of 9 September (after 18 UTC) about 38.000 flashes were recorded by LINET. On
201 10 September about 290.000 flashes were recorded over Italy, following the movement of the storm
202 propagating from NW to SE. So, more than 300.000 flashes were recorded from 18 UTC on 09
203 September to 00 UTC on 11 September, which are more than three times those recorded for Serano.
204 Thermal infrared satellite images (channel, 10.8 micron; Figure 9) show the extension of the cloud
205 coverage every 12 hours. It is well evident the cloud system associated with the cold front over
206 Europe. More specifically, the satellite image at 00 UTC shows the cloud system over Livorno area
207 (red circle in Figure 9b), before the most intense precipitation period over Tuscany (00-06 UTC),
208 while Figure 9c shows the cloud system over Central Italy (orange circle), at the end of the period
209 of intense precipitation over Lazio (06-12 UTC).

210 We conclude the synoptic analysis of the case study with two CAPPI at 3 km observed by the radar
211 network of the Department of Civil Protection. The CAPPI in Figure 10a, at 00 UTC on 10 September,
212 shows the cloud system over Tuscany with reflectivity factor up to 40 dBz. Other clouds cause
213 rainfall over northern Italy. The CAPPI of Figure 10a is the last assimilated by the 00-03 UTC VSF on
214 10 September shown in Section 4.2.1.

215 Figure 10b shows the CAPPI of the national radar mosaic at 3 km above the sea level and at 06 UTC.
216 The cloud system is moving towards Central Italy with reflectivity up to 45 dBz. Other cloud systems
217 are apparent over northern Italy. Figures 10a-10b well represent the movement of the storm
218 towards SE and Figure 10b shows the last CAPPI assimilated by the 06-09 UTC VSF shown in Section
219 4.2.2.

220

221 **3.Data and Methods**

222 *3.1 RAMS@ISAC and simulations set-up*

223 The RAMS@ISAC is used as NWP driver in this work. The model is based on the RAMS 6.0 model
224 (Cotton et al., 2003) with the addition of four main features, as well as a number of minor
225 improvements. First, it implements additional single moment microphysical schemes, whose

226 performance is shown in Federico (2016): among them, the WSM6 (Hong and Lim, 2006) is used in
227 this paper. Second, it predicts the occurrence of lightning following the diagnostic method of Dahl
228 et al. (2011), the implementation being discussed in Federico et al. (2014). Third, the model
229 assimilates lightning through nudging (Fierro et al., 2012, 2015; Federico et al., 2017a). Fourth, the
230 model implements a 3D-Var data assimilation system (Federico, 2013, hereafter also RAMS-3DVar),
231 whose extension to the radar reflectivity factor is presented in this paper (Section 3.3).

232 The list of the physical parameterisation schemes used in the simulations of RAMS@ISAC is shown
233 in Table 1.

234 Considering the domains and the configuration of the grids (Figure 11 and Table 2), two different
235 set-ups are used for Serano and Livorno. For the first case, we use the domains D1 and D2, while for
236 Livorno we use also the domain D3. The first domain covers a large part of Europe and extends over
237 the North Africa. Grid horizontal resolution is 10 km (R10). The second domain covers the whole
238 Italy and part of Europe and the grid has 4 km horizontal resolution (R4). The third domain covers
239 the Tuscany Region, has 4/3 km horizontal resolution (R1), and it is used for Livorno to represent
240 with higher spatial detail the precipitation field over Tuscany. The fine structures of the precipitation
241 field are smeared out over Tuscany using only domains D1 and D2. The operational implementation
242 of the RAMS@ISAC model uses the domains D1 and D2 and no refinements for specific areas of Italy
243 are used because Italy is a complex orography country and grid refinements for a specific event can
244 be done only a-posteriori, i.e. after the occurrence of the event.

245 All domains share the same vertical grid. It covers the troposphere and the lower stratosphere.
246 Vertical levels are more packed close to the ground. Among the 36 levels used in this paper 10 are
247 below 1 km, 14 below 2 km and 17 below 3 km. The first vertical level is at 50 m above the surface
248 in the terrain following coordinates used by RAMS@ISAC, the level 21 is at 5122 m. Above 6 km the
249 model levels are about 1000 m apart, while the maximum allowed distance between two levels is
250 1200 m. The complete list of the vertical levels is shown in the supplemental material of this paper
251 (Table S2).

252 The vertical grid is the same as the operational setting of RAMS@ISAC and is a compromise between
253 vertical resolution and computing time. The number of vertical levels will be increased to 42, starting
254 from September 2019, to better resolve the phenomena in this direction (Planetary Boundary Layer
255 processes, vertical motions, interaction between air masses and orography etc.), nevertheless the
256 current setting was successfully applied to the forecast of several heavy precipitation events over
257 Italy. A sensitivity test, using 42 vertical levels for the Livorno case, shows similar results to those

258 reported in the next section. Details on this simulation can be found in the supplemental material
259 of this paper.

260 The nesting between the first and second domains is one-way, while the nesting between the
261 second and the third domains is two-way.

262 VSF is implemented as shown in Figure 12. First a run with R10 configuration is performed using the
263 0.25° horizontal resolution GFS analysis/forecast cycle issued at 12 UTC as initial and boundary
264 conditions. R10 run, which starts at 12 UTC on 16 September for Serano and at 12 UTC on 09
265 September for Livorno, lasts 36 h and doesn't assimilate neither radar reflectivity factor nor
266 lightning. The R10 run is not updated after the acquisition of new data by the analysis system and
267 this is a limitation of the results shown in this paper. However, a sensitivity test for Livorno case
268 study shows that this limitation doesn't have a significant impact on the results presented in the
269 next Section. Details on this experiment can be found in the supplemental material of this paper.

270 Starting from 12 UTC, ten VSF are performed using R4 for Serano and both R4 and R1 for Livorno.
271 The VSF lasts 9h and uses R10 simulation as initial and boundary conditions (one-way nesting). The
272 9h forecast is divided into two parts: the first six hours are the assimilation stage when RAMS@ISAC
273 simulation is adjusted by data assimilation, whereas the last three hours are the forecast stage,
274 without data assimilation. During the assimilation stage, flashes are assimilated by nudging (Section
275 3.2), while radar reflectivity factor is assimilated every one-hour by RAMS-3DVar (Section 3.3).

276 It is noted that data assimilation is performed over the domain D2 (R4) only, and the innovations
277 are transferred to the domain D3 (R1), for the Livorno case, by the two way-nesting. The domain D3
278 is used for the Livorno case to refine the resolution of the precipitation field over Tuscany and to
279 show the spatial and temporal precision of the precipitation forecast over Tuscany using data
280 assimilation. However, its usage is exceptional because, as stated above, Italy is a complex
281 orography country and grid refinements for specific areas are used only after the occurrence of the
282 event. For this reason, the domain D3 is usually not used in RAMS@ISAC and no statistics about the
283 background error are available for this grid.

284 Because lightning and radar reflectivity factor are cloud scale observations, their assimilation at
285 higher horizontal resolution by 3D-Var is foreseeable in future works.

286 The verification of the VSF for precipitation is done by visual comparison of the model output with
287 the raingauge network of the Department of Civil Protection, which has more than 3000 raingauges
288 all over Italy.

289 In addition we consider the FBIAS (Frequency Bias; range $[0, +\infty)$), where 1 is the perfect score, i.e.
 290 when no misses and false alarms occur), POD (Probability of Detection; range $[0, 1]$, where 1 is the
 291 perfect score and 0 the worst value), ETS (Equitable Threat Score; range $[-1/3, 1]$, where 1 is the
 292 perfect score and 0 is a useless forecast), TS (Threat Score; range $[0, 1]$ where 1 is the perfect score
 293 and 0 the worst value). Scores are computed from 2x2 dichotomous contingency tables (Wilks,
 294 2006) for different rainfall thresholds and for different neighbourhood radii. Moreover,
 295 performance diagrams (Roebber, 2009) are used to summarise the scores.

296
 297 *3.2 Lightning data assimilation*

298 Lightning data are provided by LINET (Lightning detection NETWORK; Betz et al., 2009;
 299 www.nowcast.de) which has more than 500 sensors worldwide with the greatest density over
 300 Europe (more than 200 sensors). The network has a good coverage over Central Europe and
 301 Western Mediterranean (from 10 W to 35 E and from 30 N to 60 N). The area of good coverage
 302 includes the region considered in this paper.

303 LINET exploits the VLF/LF electromagnetic bands and provides measurements of both intra-cloud
 304 (IC) and cloud to ground (CG) discharges. IC strokes are detected as long as lightning occurs within
 305 120 km from the nearest sensor thanks to an optimised hardware and advanced techniques of data
 306 processing (TOA-3D, Betz et al., 2004). According to Betz et al. (2009), LINET has a location accuracy
 307 of 125 m for an average distance of 200 km among the sensors verified by strikes into towers of
 308 known positions.

309 The good performance of the LINET network and its ability to detect IC strokes is shown in
 310 Lagouvardos et al. (2009) for a storm in southern Germany, while the good performance over Italy,
 311 including both CG and IC strokes, is discussed in Petracca et al. (2014).

312 The lightning data assimilation scheme is that of Fierro et al. (2012; 2014; 2015) and uses the total
 313 lightning, i.e. intra-cloud plus cloud to ground flashes.

314 The method starts by computing the water vapour mixing ratio q_v :

$$315 \quad q_v = Aq_s + Bq_s \tanh(CX)(1 - \tanh(Dq_g^\alpha)) \quad (1)$$

316 Where coefficients are set to $A=0.86$, $B=0.15$, $C=0.30$, $D=0.25$, $\alpha=2.2$, q_s is the saturation mixing ratio
 317 at the model atmospheric temperature, and q_g is the graupel mixing ratio (g kg^{-1}). X is the number
 318 of total flashes (IC+CG) falling in a grid box of domain $D2$ ($R4$) in the past five minutes. The mixing
 319 ratio q_v of Eq. (1) is computed only for grid points where flashes are recorded. More specifically, for
 320 each grid point we consider the number of flashes falling in a grid box centred at the grid point in

321 the last five minutes. The mixing ratio of Eqn. (1) is compared with that predicted by the model. If
322 the mixing ratio of Eqn. (1) is larger than the simulated one, the latter is nudged towards the value
323 of Eqn. (1), otherwise the modelled mixing ratio is left unchanged. This method can only add water
324 vapour to the forecast.

325 The check and eventual substitution of the water vapour is performed every five minutes and it is
326 made within the mixed phase layer zone (0 °C, -25°C), wherein electrification processes caused by
327 the collision of ice and graupel are the most active (Takahashi 1978, Emersic and Sounders, 2010;
328 Fierro et al., 2015).

329 The scheme of Fierro et al. (2012; 2015) was adapted to RAMS@ISAC in Federico et al. (2017a). In
330 particular, the coefficient C of Eqn. (1) was rescaled from that of Fierro et al. (2012) considering the
331 different spatio-temporal resolution of gridded lightning data; then the coefficient C was tuned
332 (increased) by trials and errors considering two case studies of HyMeX-SOP1 (15 and 27 October
333 2012). The C constant was adapted subjectively as a compromise of increasing the hits and
334 minimising false alarms. POD and ETS scores were considered as metrics for this purpose. Then, Eqn.
335 (1) was applied to twenty case studies of HyMeX-SOP1 giving a statistically significant (90, or 95%
336 depending on the rainfall threshold) improvement of the RAMS@ISAC precipitation VSF (3h).

337 Nevertheless, a definitive statistic on the performance of rainfall VSF to nudging formulation in
338 RAMS@ISAC is missing and further studies are needed in this direction. Also, the optimal choice of
339 the coefficients A, B, C, D and α is case dependent.

340 Fierro et al (2012) applied the method using the ENTLN network, which has a detection efficiency
341 (DE) greater than 50% for IC over Oklahoma, where the ENTLN data were used. The emphasis on IC
342 flashes in the set-up of Fierro et al. (2012) is given because observational and model studies have
343 provided evidence that IC flashes correlate better than CG flashes with various measures of
344 intensifying convection (updraft strength, volume, graupel mass flux etc.; MacGorman et al. 1989;
345 Carey and Rutledge 1998; MacGorman et al. 2005; Wiens et al. 2005; Kuhlman et al. 2006; Fierro et
346 al. 2006; Deierling and Petersen 2008; MacGorman et al. 2011). For these reasons methods using
347 both IC and CG flashes perform better than those using CG only, being CG flashes correlated with
348 the descent of reflectivity cores and the onset of the demise of the storm' s updraft core
349 (MacGorman and Nielsen, 1991).

350 The analysis of the case studies shows that IC strokes are about 30% of the total number of strokes
351 reported by LINET. Also, the fraction of IC strokes to the total strokes depends on the position. For

352 example, for the Serano case, the fraction of IC strokes detected by LINET over the area hit by the
353 largest precipitation is more than 50% while over the Adriatic Sea it decreases to 10%.
354 It is also noted that DE for IC strokes cannot be reliably compared between LINET and ENTLN,
355 because the area is different and the technical details about IC detection remain unclear (type of
356 signals, VLF/LF or VHF, discrimination IC-CG).

357 For all the above reasons the application of the Fierro method to RAMS@ISAC is not straightforward
358 and it is appropriate to study the dependence of the rainfall VSF to the nudging formulation. This
359 subject is studied in the supplemental material of this paper (Section S.3) and the results show that
360 the choice of the coefficient of Eqn. (1) used in this paper is reasonable.

361 It is finally noted that despite the limitations noted above, the lightning data assimilation, with the
362 setting of this paper, had a significant and positive impact on RAMS@ISAC rainfall VSF (Federico et
363 al., 2017a; 2017b).

364

365

366 *3.3 Radar data assimilation*

367 The method assimilates CAPPI of radar reflectivity factor operationally provided by the Italian
368 Department of Civil Protection (DPC). Radar data are provided over a regular Cartesian grid with 1
369 km horizontal resolution and for three vertical levels (2, 3, 5 km above the sea level). The CAPPIs at
370 2, 3, and 5km can be considered as under-sampled vertical profiles. CAPPIs are composed starting
371 from the 22 radars of the Italian Radar Network (Figure 13) 19 operating at the C-band (i.e., 5.6 GHz)
372 and 3 at X-band (i.e., 9.37 GHz). Data quality control and CAPPI composition is performed by DPC.
373 Data quality processing chain aims at identifying most of the uncertainty sources as clutter, partial
374 beam blocking and beam broadening. The radar observations are processed according to nine steps
375 detailed in Vulpiani et al. (2014), Petracca et al. (2018) and references therein.

376 Radial velocity is not assimilated into RAMS@ISAC because it is not operationally processed, the
377 scan strategy being optimized for QPE purposes. Furthermore, the implementation of a radial
378 velocity data assimilation scheme is under development in RAMS-3DVar and it is not currently
379 available for testing. For these reasons, we didn't consider the assimilation of this parameter.

380 Before entering data assimilation, the Cartesian grid is downscaled to 5 km by 5 km in order to
381 reduce the numerical cost of the data assimilation and the effect of correlated observation errors
382 (Rohn et al., 2001). Thus, the radar grid (Figure 4, for example) is a Cartesian grid with 5 km grid-
383 spacing and three vertical levels.

384 It is important to note that pure sampling of the data could result in implementation of errors (for
 385 example reflectivity given by insects or birds) or extremes. Creating superobservations would
 386 reduce this problem, the main drawback being the missing of very localised phenomena. While the
 387 aim of this paper is to present the update of the data assimilation system of RAMS@ISAC and its
 388 application to two challenging cases, the problem of using superobservations will be considered in
 389 future studies because it impacts the results.

390 The methodology to assimilate radar reflectivity factor is that of Caumont et al. (2010), named
 391 1D+3DVar, which is a two-step process: first, using a Bayesian approach inspired to GPROF (Goddard
 392 Profiling Algorithm; Olson et al., 1996; Kummerow et al., 2001), 1D pseudo-profiles of model
 393 variables are computed, then those pseudo-profiles are assimilated by 3DVar. Both steps are
 394 discussed below.

395 The first step computes a pseudo-profile of relative humidity weighting the model profiles of relative
 396 humidity around the radar profile (Bayesian approach). The pseudo-profile is computed by:

$$397 \quad \mathbf{z}_o^p = \frac{\sum_i \mathbf{RH}_i W_i}{\sum_j W_j} \quad (2)$$

398 Where \mathbf{RH}_i is the RAMS@ISAC vertical profile of relative humidity at a grid point inside a square of
 399 $50 \times 50 \text{ km}^2$ centred at the radar vertical profile, W_i is the weight of each profile and \mathbf{z}_o^p is the relative
 400 humidity pseudo-profile. The weights are determined by the agreement between the simulated and
 401 observed reflectivity factor:

$$402 \quad W_i = \exp \left\{ -\frac{1}{2} [\mathbf{z}_o - h_z(x_i)]^T \mathbf{R}_z^{-1} [\mathbf{z}_o - h_z(x_i)] \right\} \quad (3)$$

403 Where h_z is the forward observation operator, transforming the background column \mathbf{x}_i into the
 404 observed reflectivity factor. The forward radar observation operator is taken from the RIP
 405 (Read/Interpolate/Plot) software ([https://dtcenter.org/wrf-](https://dtcenter.org/wrf-nmm/users/OnLineTutorial/NMM/RIP/index.php)
 406 [nmm/users/OnLineTutorial/NMM/RIP/index.php](https://dtcenter.org/wrf-nmm/users/OnLineTutorial/NMM/RIP/index.php), last access 03 March 2019) and is given in the
 407 supplemental material of this paper (Section S8). It assumes a Marshall-Palmer hydrometeors size-
 408 distribution, Rayleigh scattering, and depends on the mixing ratios of rain, graupel and snow.

409 The matrix \mathbf{R}_z in Eqn. (3) is diagonal and its value is $n\sigma^2$, where σ is 1 dBz and n is the number of
 410 available observations in the vertical profile (from 1 to 3). In this way, we give more weight to
 411 vertical profiles containing more data.

412 The error of radar data is assumed small (1dBz) for two reasons: a) reflectivity data are carefully
 413 checked by the Civil Protection Department; b) the performance of control simulation, not
 414 assimilating any data, is rather poor for the case studies. This setting, however, could not be optimal
 415 for cases when the control forecast performs better. A sensitivity test using $\sigma=5$ dBz for the Livorno
 416 case showed small differences compared to $\sigma=1$ dBz. The results of this sensitivity test are detailed
 417 in the supplemental material of this paper (Section S4).

418 It is important to point out that the 50 km length-scale of the above step doesn't represent the
 419 horizontal correlation length-scale of the background error, which determines the horizontal spread
 420 of the innovations in the 3D-Var data assimilation (the latter length-scale is between 14 and 25 km
 421 depending on the level). The 50 km length-scale is used to set a square for computing the pseudo-
 422 profile of relative humidity (Eqn. (2)). This profile is given by a weighted average whose weights are
 423 determined by the agreement between the simulated and observed reflectivity factor. The larger
 424 the agreement the larger the weight. This distance is appropriate because the spatial error of
 425 meteorological models in simulating meteorological features, for example fronts, can be of this
 426 order. The control simulation of the two events considered in this paper confirms this choice.

427 The method is not able to force convection when the model has no rain, snow or graupel in a square
 428 around (50*50 km²) a radar profile with reflectivity factor greater than zero. In this case, the pseudo-
 429 profile of relative humidity is assumed saturated above the lifting condensation level and with no
 430 data below (Caumont et al., 2010).

431 It is also noted that the method is able to reduce spurious convection when the reflectivity factor is
 432 simulated but not observed, because the pseudo-profile of relative humidity gives more weight to
 433 the drier relative humidity profiles simulated by RAMS@ISAC inside the 50*50 km² square centred
 434 at the radar profile. Of course, the ability to reduce spurious convection depends on the availability
 435 of dry model profiles around the specific radar profile (see the example below). Finally, if the
 436 observed profile is dry and the profile simulated by RAMS@ISAC is dry too, the pseudo-profile is not
 437 computed.

438 In summary, pseudo-profiles are computed for each profile of the radar grid whenever reflectivity
 439 is observed or simulated.

440 The pseudo-profiles computed with the procedure introduced above, are then used as observations
 441 in the RAMS-3DVar data assimilation (Federico, 2013), minimising the cost-function:

$$442 \quad J(\mathbf{x}) = \frac{1}{2} (\mathbf{x} - \mathbf{x}_b)^T \mathbf{B}^{-1} (\mathbf{x} - \mathbf{x}_b) + \frac{1}{2} (\mathbf{z}_o^p - h(\mathbf{x}))^T \mathbf{R}^{-1} (\mathbf{z}_o^p - h(\mathbf{x})) \quad (4)$$

443 Where \mathbf{x} is the state vector giving the analysis when J is minimized, \mathbf{x}_b is the background, \mathbf{B} and \mathbf{R}
444 are the background and observations error matrices, \mathbf{z}_o^p is the pseudo vertical profile computed by
445 Eqn. (2) and h is the forward observation operator transforming the state vector (RAMS@ISAC water
446 vapour mixing ratio) into observations. The cost function in RAMS-3DVar is implemented in
447 incremental form (Courtier et al., 1994) and its minimization is performed by the conjugate-gradient
448 method (Press et al., 1992). No multi-scale approach is used.

449 The background error matrix is divided into three components along the three spatial directions (x ,
450 y , z). The \mathbf{B}_x and \mathbf{B}_y matrices account for the spatial correlation of the background error. The
451 correlations are Gaussian with length-scales between 14 and 25 km, depending on the vertical level.
452 These distances are computed using the NMC method (Barker et al., 2012) applied to the HyMeX-
453 SOP1 (Hydrological cycle in the Mediterranean Experiment – First Special Observing Period occurred
454 in the period 6 September-6 November 2012; Ducroq et al., 2014) period. It is again stressed that
455 the spread of the innovations along the horizontal spatial directions in the 3D-Var analysis is
456 determined by the length scales of \mathbf{B}_x and \mathbf{B}_y matrices and varies between 14 and 25 km, depending
457 on the level.

458 The \mathbf{B}_z matrix contains the error for the water vapour mixing ratio, which is the control variable used
459 in RAMS-3DVar. This error is about 2 g/kg at the surface and decreases with height. In particular, it
460 is larger than 0.5 g/kg below 4 km, and less than 0.2 g/kg above 5 km. The vertical decorrelation of
461 the background error depends on the level and can be roughly estimated in 500-2000 m. The
462 observation error matrix \mathbf{R} in Eqn. (4) is diagonal and observations' errors are uncorrelated. This
463 choice is partially justified by under sampling the radar reflectivity factor observation by choosing
464 one point every five grid points in both horizontal directions of the radar Cartesian grid. However,
465 correlation observations errors have significant impact on the final analysis, as shown for example
466 in Stewart et al. (2013), and different choices of the matrix \mathbf{R} will be considered in future studies.

467 The value of the elements on the diagonal of \mathbf{R} depends on the vertical level and are 1/4 of the
468 diagonal element of the \mathbf{B}_z matrix at the corresponding height. With these settings, larger weights
469 are given to the observations than to the background and analyses strongly adjust the background
470 towards observations. The background error matrix is computed using the NMC method (Parrish
471 and Derber, 1992; Barker et al. 2004) applied to the HyMeX-SOP1 (Hydrological cycle in the
472 Mediterranean Experiment – First Special Observing Period occurred from 6 September to 6
473 November 2012; Ducroq et al., 2014). This choice is motivated by the fact that HyMeX-SOP1
474 contains several heavy precipitation events over Italy and the background error matrix is

475 representative of the convective environment of the cases considered in this paper. In particular,
476 10 out of 20 declared IOP (Intense Observing Period) of HyMeX-SOP1 occurred in Italy (Ferretti et
477 al., 2014). In contrast, the period of September 2017, especially before the events selected in this
478 study was characterised by fair and stable weather conditions over Italy and the background error
479 matrix for September 2017 is less representative of the convective environment that characterise
480 the events of this paper.

481 Because it is the first time that we show the assimilation of radar reflectivity factor in RAMS@ISAC,
482 it is useful to discuss an example of analysis. We select the analysis of Livorno case study at 06 UTC.
483 The observed CAPPI at 3km above sea level is shown in Figure 10b. The corresponding CAPPI
484 simulated by the background is shown in Figure 14a. In general, the comparison between simulated
485 and observed reflectivity factor highlights the difficulty of the model to represent convection
486 properly. In particular, the model is able to represent the convection over Northern Italy but it has
487 poor performance over Sardinia, south of Sicily and over Central Italy. The difference between the
488 analysis and background relative humidity after and before the analysis is shown in Figure 14b
489 (absolute values less than 1% are suppressed in the figure for clarity). Both positive (convection
490 enhancing) and negative (convection suppressing) adjustments are found. Over Central Italy,
491 Sardinia and South of Sicily relative humidity is increased because the model doesn't simulate the
492 observed reflectivity (Figure 10b). The occurrence of this condition added most of the water vapour
493 to the RAMS@ISAC simulation for the case studies of this paper. Over northern Italy the model is
494 partially dried for two different reasons: over northwest of Italy because RAMS@ISAC simulates
495 unobserved reflectivity, over north and northeast of Italy because the model simulates larger values
496 of reflectivity factor compared to the observations. The RAMS-3DVar reduces the relative humidity
497 field north of Corsica island, where the RAMS@ISAC predicts unobserved reflectivity, while RAMS-
498 3DVar didn't suppress the unobserved convection west of Sardinia because the pseudo profiles
499 computed over this area weren't appreciably drier than the background. Cross correlations among
500 different variables of the data assimilation system are neglected in this study and the application of
501 the RAMS-3DVar affects the water vapour mixing ratio only. Cross correlations among different
502 variables can improve the performance of data assimilation system, and an example of their impact
503 in the RAMS-3DVar is shown in Federico (2013). Nevertheless, the impact of cross correlations
504 among different variables in the precipitation VSF will be explored in future works.

505 Because also lightning data assimilation adjusts the water vapour mixing ratio, it follows that the
506 data assimilation presented in this study adjusts only this parameter.

507 Despite the fact that both radar reflectivity factor and lightning adjust the water vapour mixing ratio,
508 different impacts on the VSF can be expected *a-priori* because radar reflectivity factor and lightning
509 are different types of observations and because they are used in different ways in the data
510 assimilation system.

511 In particular, lightning is recorded when deep convection develops, while radar reflectivity factor is
512 observed also for light stratiform rain. Flashes of ground based network, as LINET, are available over
513 the open sea, even if with a reduced detection efficiency, while radar reflectivity factor is confined
514 to the range of coastal radars in the network. Lightning has a seasonal dependence over Italy, with
515 the maximum in summer and fall, while radar reflectivity factor is available in all seasons.

516 Also, differences in data assimilation of lightning and radar reflectivity factor play a role. In addition
517 to the methods used to assimilate observations, lightning saturates the layer 0°C/-25°C where/when
518 it is detected, while radar reflectivity factor can be assimilated by pseudo-profiles or by saturation
519 above the lifting condensation level where observed reflectivity is greater than zero.

520 So, despite both observations adjust the same model prognostic variable, which is a drawback of
521 the methodology presented in this paper, the impacts of lightning and radar reflectivity factor is
522 expected to be different as will be evident from the results of this paper.

523 There are, however, advantages using the methodology presented in this paper. In addition to being
524 simple, it doesn't rely on approximate relationship between radar reflectivity factor with
525 hydrometeors mixing ratio, leaving to the model the task of evolving the water vapour
526 added/subtracted. Also, the impact of the data assimilation on model results are substantial (Fabry
527 and Sun, 2010; Caumont et al., 2010), as also shown by the results of this paper.

528 Lightning and radar data assimilation may produce sharp gradients in vertical direction caused by
529 the addition of water vapour to specific layers. In the case of lightning, the water vapour is added
530 by nudging to reduce sharp gradients. However, radar data assimilation, which accounts for the
531 largest mass of water added to RAMS@ISAC (see Section S.2 of the supplemental material), directly
532 adjusts the water vapour into the model. Our experience with RAMS@ISAC, however, shows that
533 results are reliable and the sudden addition of water vapour doesn't cause shocks to the model
534 simulation, despite the notable gradients of specific humidity.

535 It is finally noted that the data assimilation increase/decrease the water vapour into the model
536 depending on the cases. The eventual increase/decrease of the forecasted rainfall depends on the
537 physical and dynamical processes occurring into the meteorological model, without any specific
538 tuning.

539

540 **4. Results**

541 In this section, we discuss the most intense phase of the Serano case, 03-06 UTC on 16 September,
542 and two VSF forecasts, 00-03 UTC and 06-09 UTC on 10 September, for the Livorno case. The two
543 VSF for Livorno correspond to the most intense phase of the storm in Livorno and to a very intense
544 phase over Lazio region, Central Italy. The aim of the section is to show the notable improvement
545 given by lightning and radar reflectivity factor data assimilation to the VSF.

546 We consider four types of VSF (Table 3): a) CTRL, without radar reflectivity factor and lightning data
547 assimilation; b) LIGHT, assimilating lightning but not radar reflectivity factor; c) RAD, assimilating
548 radar reflectivity factor but not lightning; d) RADLI, assimilating both lightning and radar reflectivity
549 factor.

550 Several aspects of lightning and radar reflectivity factor data assimilation are considered in the
551 supplemental material of this paper: a) the relative contribution to the total water mass given by
552 lightning and radar reflectivity factor data assimilation (Section S.2); b) the sensitivity of the
553 precipitation VSF to the nudging formulation (Section S.3); c) the sensitivity of rainfall VSF to two
554 specific aspects of radar reflectivity factor data assimilation (Section S4); d) the sensitivity of rainfall
555 VSF to RAMS@ISAC setting (Section S5); e) the impact of lightning data assimilation for a case study
556 well predicted by the control forecast (Section S6); f) different plots of Figures 15-17 (Section S7)
557 and g) the forward radar operator used in RAMS-3DVar (Section S8).

558

559 *4.1 Serano: 03-06 UTC on 16 September 2017*

560 In this period, an intense and localised storm hit central Italy, while light precipitation occurred over
561 northern Italy (Figure 15a). Considering the storm over central Italy, 10 raingauges observed more
562 than 30 mm/3h, 6 more than 40 mm/3h, 3 more than 50 mm/3h and 1 more than 60 mm/3h, the
563 maximum observed value being 63 mm/3h.

564 The CTRL forecast, Figure 15b, misses the storm over central Italy and considerably underestimates
565 the precipitation area over Northern Italy, giving unsatisfactory results.

566 The assimilation of the radar reflectivity factor improves the forecast, as shown in Figure 15c. In
567 particular, RAD forecast shows localized precipitation (30-35 mm/3h) close to the area where the
568 most abundant precipitation was observed. Maximum precipitation is underestimated. Also, the
569 RAD forecast better represents the precipitation over Northern Italy compared to CTRL.

570 The rainfall forecast of LIGHT, Figure 15d, shows some improvements compared to CTRL because
571 the precipitation over central Italy has a maximum of 25-30 mm/3h, close to the area where the
572 maximum precipitation was observed. LIGHT, however, has a worse performance compared to RAD
573 because it underestimated the precipitation area over northern Italy. LIGHT underestimates the
574 maximum precipitation in central Italy.

575 RADLI forecast, Figure 15e, has the best performance. The precipitation over central Italy is well
576 represented because the maximum rainfall (40-45 mm/3h) is in reasonable agreement with
577 observations, and also because the area of intense precipitation (> 25 mm/3h) is elongated in the
578 SW-NE direction in agreement with raingauge observations. The precipitation over northern Italy is
579 well represented by RADLI.

580 Performance diagram for 1 mm/3h and 30 mm/3h and for 4 km and 25 km neighbourhood radii is
581 shown in Figure 15f. Different radii are considered to account for the well-known double penalty
582 error (Mass et al., 2002; Mittermaier et al., 2013) caused by displacement errors of the detailed
583 precipitation forecast in convection allowing grids. RADLI has the best performance thanks to the
584 synergistic contribution of lightning and radar reflectivity factor data assimilation.

585

586 *4.2 Livorno*

587 The Livorno case study lasted for several hours starting at 18 UTC on 9 September 2017 and ending
588 more than a day later. The most intense phase in Livorno and its surroundings was observed during
589 the night between 9 and 10 September. In the following, we will show two representative VSF (3h),
590 including the most intense phase in Livorno.

591

592 *4.2.1 Livorno: 00-03 UTC on 10 September 2017*

593 This period represents the most intense phase of the storm in Livorno. In particular, the raingauge
594 close to the label A (Figure 16a) reported 151 mm/3h (Collesalveti), while the one close to the label
595 B measured 82 mm/3h. Among the 518 raingauges reporting valid data, 75 observed more than 10
596 mm/3h, 31 more than 20 mm/3h, 17 more than 30 mm/3h, 9 more than 40 mm/3h, and 6 more
597 than 50 mm/3h.

598 The CTRL precipitation forecast is shown in Figure 16b. The forecast is poor because it misses the
599 precipitation swath from the coast towards NE. A precipitation swath is forecasted about 50 km to
600 the North of the real occurrence, but it is less wide compared to the observations.

601 The RAD forecast, Figure 16c, shows that the assimilation of radar reflectivity factor gives a clear
602 improvement to the forecast. The largest precipitation in the coastal part of the swath (we searched
603 for the maximum in the area with longitudes between 10.20E and 10.70E and latitudes between
604 43.10N and 43.60N) is 94 mm/3h. Another local maximum is in the southern part of the domain
605 (label B of Figure 16a). The maximum location is well represented, but the forecast value (55
606 mm/3h) underestimates the observed maximum (82 mm/3h).

607 An improvement, compared to both CTRL and RAD, is given by the assimilation of lightning (Figure
608 16d). The maximum value close to Livorno, i.e. in the coastal part of the swath, is 158 mm/3h.
609 LIGHT simulation shows the local maximum in the southern part of the domain (about 50 mm/3h),
610 but the amount is underestimated.

611 Figure 16e shows the RADLI rainfall forecast. The precipitation swath from coastal Tuscany towards
612 NE is more intense compared to LIGHT and RAD. The maximum rainfall accumulated close to Livorno
613 is 186 mm/3h. Also, the second precipitation maximum in the southern part of the domain reaches
614 70 mm/3h in good agreement with observations (82 mm/3h). RADLI is the only run giving a
615 satisfactory precipitation VSF over the south-eastern Emilia Romagna (north-eastern part of the
616 domain), to the lee of the Apennines. It is also noted that the main precipitation swath forecasted
617 by RADLI is too broad in the direction crossing the swath compared to the observations. This is
618 confirmed by the FBIAS of RADLI (not shown), which is more than 3 for thresholds larger than 42
619 mm/3h.

620 The performance diagram (Figure 16f) shows that LIGHT has better scores than RAD for this VSF.
621

622 *4.2.2 Livorno: 06-09 UTC on 10 September 2017*

623 In this period, the most intense precipitation occurred over the coastal part of Lazio (Figure 17a).
624 More in detail, among the 2695 raingauges reporting valid data over the domain of Figure 17a, 307
625 reported more than 10 mm/3h, 132 more than 20 mm/3h, 86 more than 30 mm/3h, 66 more than
626 40 mm/3h, 49 more than 50 mm/3h and 35 more than 60 mm/3h. Among the 35 raingauges
627 measuring more than 60 mm/3h, 33 were over Lazio, showing the heavy rainfall occurred over the
628 Region.

629 Some precipitation persisted over Tuscany but the rainfall is much lower compared to previous 6h
630 (the rainfall over Tuscany between 03 and 06 UTC was very intense, not shown).

631 Figure 17b shows the rainfall simulated by CTRL. The forecast is unsatisfactory, mainly for the
632 following two reasons: a) heavy precipitation is simulated over Tuscany (> 75 mm/3h), also close to

633 the Livorno area; b) precipitation is missed over central Italy. The rainfall over NE of Italy is well
634 represented in space, but overestimated.

635 Considering the evolution of CTRL forecast for the two VSF of Livorno, we conclude that it was able
636 to predict abundant rain over Livorno, but the rainfall forecast was delayed compared to the real
637 occurrence. A similar behaviour was found in Ricciardelli et al. (2018) using the WRF model, showing
638 that the results of this paper for Livorno are likely not tied to the specific model used.

639 The rainfall simulated by RAD (Figure 17c) clearly improves the forecast compared to CTRL. First,
640 the precipitation over Lazio is well predicted. Second, the precipitation over Tuscany is less than for
641 CTRL, showing the ability of radar reflectivity factor data assimilation to dry the model when it
642 predicts reflectivity that is not observed. This is confirmed by the inspection of the analysis of Figure
643 14b, the last analysis used before this VSF, which gives a decrease of the relative humidity over most
644 of Tuscany and over the sea in front of Livorno. It is noted, however, that the area of intense rainfall
645 (>60 mm/3h) is overestimated by RAD, showing a wet forecast. The wet bias of the RAD forecast is
646 apparent in the representation of the rainfall VSF shown in the supplemental material of this paper
647 (Figure S12).

648 LIGHT forecast, Figure 17d, shows a worse performance compared to RAD for this time period. The
649 precipitation forecast is mainly over Tuscany, where it is overestimated, with a small precipitation
650 spot over Lazio.

651 The precipitation forecast of RADLI, Figure 17e, represents very well the precipitation over Lazio,
652 and the rainfall amount is better predicted compared to RAD. The precipitation over Sardinia is well
653 represented by RADLI as well as the precipitation over Central Alps, giving the best results among
654 all VSF.

655 Figure 17f shows the better performance of RAD compared to LIGHT for this precipitation VSF. RADLI
656 has the best performance being closer to the upper right corner of the diagram.

657 To better understand the changes of the precipitation VSF to different data assimilation set-up,
658 Figure 18 shows maps of water vapour mixing ratio averaged between 3 and 10 km at the end of
659 the assimilation phase (06 UTC on 10 September 2017). It is important to note that those maps
660 contain the effects of both data assimilation and model evolution.

661 The comparison between CTRL (Figure 18a) and RAD (Figure 18b) shows that RAD has a line of high
662 water vapour values over Central Italy, extending over the Tyrrhenian Sea and Sardinia, which is not
663 simulated by CTRL. This line results from both radar data assimilation and convection, which
664 transports water vapour from lower to upper levels. The comparison between CTRL and RAD shows

665 the substantial impact of radar reflectivity factor data assimilation on the model evolution despite
666 we are not using relationship between hydrometeors mixing ratios and radar reflectivity factor in
667 data assimilation.

668 LIGHT averaged water vapour (Figure 18c) over the Tyrrhenian Sea and west of Sicily is higher
669 compared to CTRL because of lightning data assimilation and model processes. Convection develops
670 over Tuscany, northern Lazio and NE of Italy, causing the increase of averaged water vapour in those
671 areas.

672 Because RAD and LIGHT both assimilate water vapour it is important to highlight the differences
673 between the two fields. First, LIGHT it is not able to represent a compact line of high water vapour
674 over Central Italy that, in the following hours, caused high precipitation over Lazio. Second,
675 averaged water vapour simulated by RAD is larger than for LIGHT over Central Italy, which is caused
676 by a deeper convection developing in RAD than in LIGHT, as well as by the different contributions
677 of data assimilation. Finally, RADLI (Figure 18d) is similar to RAD but it shares also features with
678 LIGHT as the increase of water vapour over the Tyrrhenian Sea.

679 It is also interesting to compare vertical cross sections of relative humidity for different data
680 assimilation set-up. Figure 19 show the longitude-height cross sections of relative humidity from
681 different data assimilation configurations.

682 Comparing RAD with CTRL it is evident the difference of the relative humidity field over the
683 Tyrrhenian Sea and western part of Italy (more specifically at longitudes between 10.5 and 12.5).

684 LIGHT shows two areas with high relative humidity: west of Corsica and over the Tyrrhenian Sea.
685 The wet area west of Corsica is caused by the assimilation of lightning (Figure 8b) and it is not
686 simulated by RAD because Corsica is not well sampled by the radar network and because of different
687 model evolutions. Lightning data assimilation also increases the humidity over the Tyrrhenian Sea
688 and on the western part of Italy, as shown by the comparison with CTRL, nevertheless their effect is
689 lower compared to radar reflectivity data assimilation.

690 RADLI has features of both lightning and radar reflectivity factor data assimilation.

691 So, considering the results of Figure 18 and 19 as well as the rainfall VSF, the impact of lightning and
692 radar reflectivity factor on the VSF can be very different despite they both adjust the water vapour
693 mixing ratio.

694

695 **5. Discussion and Conclusions**

696 In this paper, we showed the impact of lightning and radar reflectivity factor data assimilation on
697 the very short term precipitation forecast (3h) for two case studies occurred in Italy. We used
698 RAMS@ISAC model, whose 3DVar extension to the assimilation of radar reflectivity factor is shown
699 in this paper for the first time.

700 The first case study occurred on 16 September 2017 and it is a moderate case with localised rainfall
701 over central Italy. It was chosen because the control forecast, i.e. without radar reflectivity factor
702 or lightning data assimilation, missed the event. The second event, occurred on 9-10 September
703 2017, was characterised by exceptional rainfall over several parts of Italy. This event was partially
704 represented by the control forecast. In particular, the forecast of the event was incorrect because:
705 a) the control forecast was delayed compared to the observations; b) the control forecast missed
706 the rainfall over central Italy (Lazio Region).

707 It is important to recall that the impact of the lightning data assimilation on the precipitation
708 forecast of RAMS@ISAC was already studied for the HyMeX-SOP1 period (Federico et al., 2017a,
709 2017b), and a robust statistic is already available. The results of this study confirm the important
710 role of the lightning data assimilation on the rainfall forecast for other two case studies. However,
711 considering the assimilation of radar reflectivity factor, and its combination with lightning data
712 assimilation in RAMS@ISAC, the results of this paper are new.

713 Because we analysed only two case studies, no definitive conclusions can be derived on the
714 performance of RAMS@ISAC for radar reflectivity factor data assimilation. There are, however, few
715 points worth of mention.

716 The VSF performance of RAMS@ISAC is systematically improved by the assimilation of radar
717 reflectivity factor. This improvement is of paramount importance for some specific VSF (for example
718 for the 00-03 UTC of Livorno), when the control forecast missed the event while it was correctly
719 predicted by radar reflectivity factor data assimilation. Sometimes the improvement of reflectivity
720 factor data assimilation has less impact on the precipitation forecast, as for the period 18-21 UTC
721 on 9 September 2017 (Livorno, not shown, see the discussion paper Federico et al. (2018) for a
722 description of this VSF). This suggests that there is room for improvement for all components of the
723 VSF: observations, data assimilation, meteorological model.

724 Lightning and radar observations are different and both add value to the VSF. Some examples have
725 been shown: the light precipitation over Northern Italy for Serano is well forecasted assimilating
726 radar reflectivity factor, while it is not simulated assimilating flashes because they are too few in
727 this area to force convection; lightning data assimilation is able to better represent the deep

728 convection occurring during the intense phase of the Livorno case (00-03 UTC), especially because
729 it is able to force convection where it occurs, reducing false alarms. The ability of lightning data
730 assimilation to reduce false alarms compared to RAD and RADLI it is shown by the fact that the ETS
731 score for LIGHT is sometimes the best among all simulations (see also the Section S2 of the
732 supplemental material of this paper). These results show also that the influence of different
733 observations depends on the meteorological situation.

734 The model configuration assimilating both radar reflectivity factor and lightning (RADLI) is able to
735 retain important features of both data assimilation. For example, the simulation of the Livorno case
736 in the phase 06-09 UTC was able to simulate the heavy precipitation over Lazio thanks to the radar
737 reflectivity factor data assimilation and the precipitation over Sardinia, as well as the moderate
738 precipitation over central Alps, thanks to lightning data assimilation.

739 The property of RADLI to retain the precipitation features of both RAD and LIGHT it is shown by the
740 POD score, which is the best, for most cases and thresholds, for RADLI.

741 Another interesting feature is the considerable improvement of the POD of RADLI compared to CTRL
742 for the lowest thresholds.

743 It is also underlined that the data assimilated, both lightning and radar reflectivity factor, are
744 available in real time and could be used for an operational implementation of the VSF.

745 It is worth noting that several sensitivity tests were conducted for the case studies, whose results
746 are shown in the supplemental material. In particular, we studied the sensitivity of the rainfall VSF
747 to: a) nudging formulation used for lightning data assimilation; b) increasing the observation error
748 of radar reflectivity factor; c) changing the shape of the searching area to compute the relative
749 humidity pseudo-profile; d) updating IC/BC as new observations are available; e) increasing the
750 vertical resolution of RAMS@ISAC by using 42 vertical levels. All these sensitivity tests confirm the
751 findings of this paper and generalise in some measure the finding of this paper.

752 The above results are promising and deserve future studies to better understand the role of radar
753 reflectivity factor data assimilation and its interaction with lightning data assimilation to improve
754 the precipitation forecast, especially at the very short range (0-3 h).

755 There are, however, less satisfactory aspects of assimilating both radar reflectivity factor and
756 lightning data. In particular, the wet bias of RAD and RADLI forecast is the main drawback of the
757 results of this paper. To reduce the moisture added by radar and lightning data assimilation further
758 research is needed and different approaches are possible (Fierro et al., 2016). In particular: a)
759 assimilating for a shorter time (0-6h in this paper); b) reducing the length-scales of the 3D-Var in the

760 horizontal directions to limit the spreading of the innovations, or assuming an innovation equal to
761 zero for grid points without lightning and with zero reflectivity factor; c) reducing the amount of
762 water vapour added to the model (for example reducing the values of A and B constants for lightning
763 data assimilation or relaxing the request of saturation when radar reflectivity is observed in areas
764 where the model has zero reflectivity); d) adding moisture to a shallower vertical layer.

765 It is also noted that a combination of heating and moistening could provide the same buoyancy with
766 less water vapour addition (Marchand and Fulberg, 2014) and this approach could be used in future
767 studies.

768 In addition to the acquisition of more case studies, there are two directions of future development
769 of this work. The lightning data assimilation can be formulated by 3DVar, using a strategy similar to
770 the radar reflectivity factor in which pseudo-profiles of relative humidity are first generated where
771 flashes are recorded, and then those profiles are assimilated by 3DVar. This methodology was
772 already reported in Fierro et al. (2016). The assimilation of both radar reflectivity factor and lightning
773 using RAMS-3DVar will be explored in future studies.

774 Another important point to study is how long the innovations introduced by data assimilation lasts
775 in the forecast. While in this study we consider the VSF at 3h, future studies must explore longer
776 time ranges. This kind of study was performed for lightning data assimilation (Fierro et al., (2015);
777 Federico et al., 2017b; Lynn et al. (2015) among others) and for radar data assimilation (Hu et al.
778 (2006); Jones et al. (2014), among others), using a rationale similar to that used in this paper.

779 In general, the performance of the forecast and the impact of lightning and radar data assimilation
780 decrease with forecasting time because boundary conditions propagate inside the domain and
781 because model errors grow and eventually become dominant. Improving the data assimilation
782 system also contributes to a longer resilience of model performance. The studies cited above
783 showed that lightning and radar data assimilation can have an impact up to 24h depending on
784 several factors (meteorological model, data assimilation, quality of the data, meteorological
785 conditions, initial and boundary conditions).

786 A study considering both radar reflectivity factor and lightning should be performed to understand
787 the resilience of the innovations introduced by data assimilation.

788

789 **ACKNOWLEDGMENTS**

790 This work is a contribution to the HyMeX program. Part of the computational time used for this
791 paper was granted by the ECMWF (European Centre for Medium range Weather Forecast)

792 throughout the special project SPITFEDE. LINET data were provided by Nowcast GmbH
793 (<https://www.nowcast.de/>) within a scientific agreement between H.D. Betz and the Satellite
794 Meteorological Group of CNR-ISAC in Rome.

795 This work was partially funded by the agreement between CNR-ISAC and the Italian Department of
796 Civil Protection.

1041 **TABLES**

1042 Table 1: RAMS@ISAC physical parameterisations used in this paper.

Physical parameterization	Selected scheme
Parametrized cumulus convection	Modified Kuo scheme to account for updraft and downdraft (Molinari and Corsetti, 1985). The scheme is applied to R10 only.
Explicit precipitation parameterization	Bulk microphysics with six hydrometeors (cloud, rain, graupel, snow, ice, water vapour). Described in Hong and Lim (2006).
Exchange between the surface, the biosphere and atmosphere.	LEAF3 (Walko et al., 2000). LEAF includes prognostic equations for soil temperature and moisture for multiple layers, vegetation temperature and surface water, and temperature and water vapour mixing ratio of canopy air.
Sub-grid mixing	The turbulent mixing in the horizontal directions is parameterised following Smagorinsky (1963), vertical diffusion is parameterised according to the Mellor and Yamada (1982) scheme, which employs a prognostic turbulent kinetic energy.
Radiation scheme	Chen-Cotton (Chen and Cotton, 1983). The scheme accounts for condensate in the atmosphere.

1043

1044 Table 2: Basic parameters of the RAMS@ISAC grids (R10, R4 and R1, corresponding, respectively, to the domains D1, D2
 1045 and D3). NNXP is the number of grid points in the WE direction, NNYP is the number of grid-points in the NS direction,
 1046 NNZP is the number of vertical levels, DX is the size of the grid spacing in the WE direction, DY is the grid spacing in the
 1047 SN direction. Lx, Ly, and Lz are the domain extensions in the NS, WE, and vertical directions. CENTLON and CENTLAT are
 1048 the coordinates of the grid centres.

1049

	R10, D1	R4, D2	R1, D3

1211 Figure 15: a) rainfall reported by raingauges between 03 and 06 UTC on 16 September 2017. Only raingauges observing
1212 at least 0.2 mm/day are shown. The first number in the title within brackets represents the available raingauges, while
1213 the second number represents those observing at least 0.2 mm/3h; b) rainfall VSF of CTRL for the same time interval
1214 as in a); c) as in b) for RAD forecast; d) as in b) for LIGHT forecast; e) as in b) for RADLI forecast; f) performance diagram:
1215 black symbols are for the nearest neighbourhood and for 1mm/3h threshold; red symbols are for the nearest
1216 neighbourhood and for 30 mm/3h threshold; blue symbols are for 25 km neighbourhood radii and for 1 mm/3h
1217 threshold; green symbols are for 25 km neighbourhood radii and for 30 mm/3h threshold.

Figure 16: a) rainfall reported by raingauges between 00 and 03 UTC on 10 September 2017. Only stations reporting at least 0.2 mm/3h are shown. The first number in the title within brackets represents the number of raingauges available over the domain, while the second number shows those observing at least 0.2 mm/3h; b) rainfall VSF of CTRL for the same time interval as in a); c) as in b) for RAD forecast; d) as in b) for LIGHT forecast; e) as in b) for RADLI forecast. Labels A and B help to identify the positions of two rainfall maxima discussed into the text; f) performance diagram: black symbols are for the nearest neighbourhood and for 1mm/3h threshold; red symbols are for the nearest neighbourhood and for 30 mm/3h threshold; blue symbols are for 25 km neighbourhood radii and for 1 mm/3h threshold; green symbols are for 25 km neighbourhood radii and for 30 mm/3h threshold.

Figure 17: a) rainfall reported by raingauges between 06 - 09 UTC on 10 September 2017. For this time period 2695 raingauges reported valid observations in the domain, however only stations reporting at least 0.2 mm/3h are shown. The first number in the title within brackets represents the number of raingauges available over the domain, while the second number shows those observing at least 0.2 mm/3h; b) rainfall VSF of CTRL in the same time interval as a); c) as in b) for RAD forecast; d) as in b) for LIGHT forecast; g) as in b) for RADLI forecast; f) performance diagram: black symbols are for the nearest neighbourhood and for 1mm/3h threshold; red symbols are for the nearest neighbourhood and for 30 mm/3h threshold; blue symbols are for 25 km neighbourhood radii and for 1 mm/3h threshold; green symbols are for 25 km neighbourhood radii and for 30 mm/3h threshold.
