9 **Abstract**

10

11 The twofold aim of this paper is to provide an overview of the current state of resilience research with
12 regard to climate change in the social sciences and propose a research agenda. Resilience research
13 among social scientists is characterized by much more diversity today than a few decades ago.
14 Different definitions and understandings of resilience appear in publications during the last ten years.
15 Resilience research increasingly bears the mark of social constructivism, a relative newcomer
16 compared to the more long-standing tradition of naturalism. There are also approaches that are
17 indebted to both “naturalism” and “constructivism”, which, of course, come in many varieties. Based
18 on our overview of recent scholarship, which is far from being exhaustive, we have identified six
19 research avenues that arguably deserve ~~continuing~~continued attention. They combine naturalist and
20 constructivist insights and approaches so that human agency, reflexivity and considerations of justice
21 and equity are incorporated into ~~systems~~systems thinking research or supplement such research.
22 Ultimately, we believe that the overarching challenge for future research is to ensure that resilience
23 to climate change does not compromise sustainability and considerations of justice (including,
24 environmental, climate and energy justice).

25

26 Keywords: adaptive resilience, climate change, just resilience, transformative resilience,
27 transformational adaptation, wicked resilience

28

29

30 **1. Introduction**

31 A brief and non-exhaustive overview of resilience scholarship published in the period 1970-2020
32 reveals a diversification of research foci and themes, approaches and methods, and theoretical
33 frameworks. Resilience has been a prevalent research topic among ecologists for several decades and,

34 very soon after, among cyberneticists. Given the association of resilience with the natural sciences and
35 engineering (cf. Indirli, 2019), it is perhaps not so surprising that most social scientists did not see the
36 need to have recourse to the terminology or concept until much later. And if they did adopt the idea
37 earlier, they were likely to embrace the naturalist theoretical framework that accompanied it (Holling,
38 1973; 2001; cf. Chandler, 2014). Other social scientists are still reluctant to accept resilience as a universal
39 and unifying concept, pointing out that the “core concepts and principles in resilience theory that create
40 theoretical tensions and methodological barriers between the natural and social sciences” (Olsson et
41 al., 2015). This conceived opposition between the natural sciences and social sciences may not be
42 experienced by all naturalists or social scientists. Even more importantly perhaps, such opposition – real or
43 surmised – may hinder fruitful collaborations in the face of our ecological crisis. Yet, collaboration,
44 integration or “transdisciplinarity” in the real worlds of universities and research institutes may not always
45 reflect a genuine transcendence of disciplinary boundaries, but instead largely consists of natural sciences
46 and engineering research in sustainability (Groß and Stauffacher, 2014). That said, there have been genuine
47 attempts to transcend the limitations of both naturalism – in the strict, technical sense of the term (Anderl,
48 2014) – and forms of social constructivism that border on relativism (Proctor, 1998a; 1998b; Popa et al.,
49 2015). Such “transdisciplinary” research is typically problem-oriented (Groß and Stauffacher, 2014).

50 Crawford Stanley Holling’s ecological notion of resilience (Holling, 1973) is considered by some
51 as a bridge between the social sciences and engineering (Ostrom, 2007; Thorén, 2014). The appeal of
52 Holling’s socio-ecological systems (SES) approach among some social scientists may be due to its being
53 a corrective to the tendency of Holling’s fellow ecologists to unconditionally embrace the methods and
54 premises inherited from classical physics (cf. Holling, 1973; Thorén, 2014; Estêvão, Calado and
55 Capucha, 2017; Davoudi, 2018). Holling corrected what he considered to be a flawed view of the world
56 and of ecosystems, namely, as closed, or stable. Against the “equilibrium-centered” view, he
57 emphasized the influence of random events (natural or human-caused) on ecological systems (Holling,
58 1973, 15). Yet, even this complex systems approach does not score very highly at the level of reflexivity,
59 which is required to discover and “acknowledge overt or covert forms of dominance shaping public

60 discourse and participation” (Popa et al., 2015). Slightly more positively framed, societal resilience to
61 climate change also involves political and institutional factors, lifestyles and consumer habits,
62 production patterns, and structures of power in general (cf. Douglas and Wildavsky, 1983; Blühdorn,
63 2013; Kolers, 2016; Fischer, 2017; Dryzek and Pickering, 2019). Resilience research that takes into
64 account such social factors (which do not necessarily obey physical laws) can be broadly classified as
65 belonging to “social constructivism”.

66 The Tsunami in 2004 and Katrina in 2005 seem to have acted as catalysts for generating more
67 resilience research among social scientists (Pizzo, 2015). This increasing interest for resilience on the
68 part of certain social scientists (and other scholars from different disciplines) cannot be detached from
69 the popularity that the terminology ~~has~~ started to gain among national governments and global
70 governance actors, including the Rockefeller Foundation, for instance, at the beginning of the new
71 century. Such tendency became stronger with the global financial crisis of 2007-2008. The widespread
72 recourse to the language of resilience by powerful private and public actors has incited a series of
73 scholarship critical of such discourse (Chandler, 2014; Pizzo, 2015; Lockie, 2016; Derickson, 2016;
74 Hilhorst 2018). The latter, it is observed, easily hides vested political and economic interests, and
75 distracts attention from structural and institutional defects by emphasizing resilience through
76 technological innovations. Katrina and, even more recently, Covid-19, it is argued, reveal a vulnerability
77 that is not simply an unavoidable fragility in the face of natural hazards, but is also the fruit of
78 institutions and political decisions over a long period of time. Natural disasters tend to be perceived
79 as indiscriminate and indifferent as to whom they affect. Yet, as Belkhir and Charlemaïne (2007, p. 12)
80 point out, “hurricanes may not single out victims by their race, or gender or class but neither do such
81 disasters occur in historical, political, social, or economic vacuums”. In other words, social, cultural,
82 political, and economic conditions are conceived to be involved in the resilience or non-resilience of a
83 nation or of particular groups to natural calamities (Henkel et al., 2006; Tierney, 2015; Lockie, 2016).

84 —————In this regard, it is interesting to take note of the discussion surrounding the terminology
85 “natural disaster” vs “disaster” (Kelman, 2020).

86 The aim of this paper is to provide an overview of the current state of resilience research with
87 regard to climate change in the social sciences and propose a research agenda. Resilience research
88 among social scientists is characterized by much more diversity today than a few decades ago.
89 Different definitions and understandings of resilience appear in publications during the last ten years
90 (cf. Indirli, 2019). Resilience research increasingly bears the mark of social constructivism, a relative
91 newcomer compared to the more long-standing tradition of naturalism. Given this history, it is hardly
92 surprising that social scientists focusing on resilience to climate change should initially have borrowed
93 the research methods common to natural and applied sciences. "Social constructivist" approaches
94 gradually made their entrance, especially in reaction to both the perceived inadequacy of particular
95 naturalistic approaches and the increasing normative use of resilience in policy agendas
96 (Weichselgartner and Kelman, 2015). There are also approaches that are indebted to both
97 "naturalism" and "constructivism" (which, of course, come in many varieties). "Ecological naturalism",
98 for instance, departing from ecological science, integrates constructivist insights about power and
99 mastery, the diversity of human knowledge, and the politics of knowledge. It thereby resists the
100 reductionistic tendencies of positivist empiricism (Code, 2005). "Critical realism" (Carolan, 2005)
101 similarly wishes to avoid the danger of reductionism while profiting from the wealth of (applied)
102 natural sciences.

Formatted: Font color: Black

103 Hence, though we acknowledge the many varieties of both "naturalism" and "constructivism"
104 and the various endeavors to transcend the limitations of both naturalism and constructivism, we
105 observe that most resilience research in the social sciences still takes place in the dialectical field
106 constituted by these two approaches, in their strict, traditional senses (cf. Andler, 2014). This is the
107 theme of the next section. But first we briefly examine how resilience research in the social sciences
108 has undergone a thorough diversification. Such diversity, however, sometimes means that research
109 takes place in parallel worlds and that there is little cross-fertilization between scholars. It is suggested
110 that social scientific inquiry into resilience in the context of climate change could be raised to a next
111 level if these two different approaches meet and interact. To this end, we reconstruct contemporary

Formatted: Indent: First line: 1,25 cm

112 debates in that particular field of studies and distil recurrent research topics that divide social
113 scientists. The issues of adaptation and transformation in the context of severe disturbances or shocks
114 that come with climate change (such as hurricanes, floods, ~~drought~~droughts, and heatwaves) appear
115 to be such divisive topics. Finally, naturalist and constructivist directions, as well as possible cross-
116 fertilizations of these two currents, for future resilience research are identified. We point out that
117 future resilience research in the social sciences – that is, the types of questions raised, theoretical
118 frameworks and modes of analysis – will also be determined by changing conditions (ecological,
119 political, and socioeconomic).

120

121 2. The diversification of resilience research in the social sciences

122 One of the earliest appearances of the term resilience – in European literature at least – seems to have
123 been in one of Aesop’s fables, namely, that of *The Oak Tree and the Reeds*. According to one of the
124 versions of that story, the Oak Tree becomes uprooted during a storm while its fellow reeds survive it.
125 In a conversation, the Oak Tree expresses its bewilderment that the fragile reeds were able to resist
126 such a mighty storm while it succumbed. The reeds reply that it is precisely their non-resistance that
127 saved them. Through their capacity to bend, they moved with the direction of the wind (which thus
128 did not break them) and rose again when the storm was gone. They were flexible enough. The reeds
129 “bounce” back and are thus “resilient”. Indeed, the English word resilience derives from Latin (*resilire*),
130 which generally meant rebounding. This Latin word can be found in the writings of Seneca the Elder,
131 Pliny the Elder, Ovid, Cicero, and Livy; -to rebound is also the sense in which *resilire* is used by Cicero
132 in his *Orations* (Alexander, 2013). The term also appears in Lucretius’ *On the Nature of Things*, where
133 it denotes “being forced back by a resisting surface [...] with reference to the action on Nature” (Pizzo,
134 2015, ~~p. 133~~). Along this line, nature compels all things to “spring off”.

135 Despite the various meanings attributed to the term, the connotation attached to *resilire* was
136 commonly that of rebounding (cf. Indirli, 2019). Up to the early nineteenth century, this was the

137 predominant understanding of resilience in common language and imagination. A slight shift appeared
138 when engineers started to use the term to refer to the properties and capacities of materials to absorb
139 tensions and release energy, and recover their original forms, without breaking or disfiguration after
140 undergoing some external shock or disturbance (such as ~~extreme weather conditions~~) (Estêvão,
141 Calado and Capucha, 2017; Bergström, 2018; Davoudi, 2018). In the 1950s, psychologists re-adapted
142 the common sense of the term to mental health and used it to study the coping mechanisms of
143 concentration camp survivors. Later, the concept is used to study various kinds of trauma, misfortune,
144 adversity, stress, and mental recovery (Bourbeau, 2015; Estêvão, Calado and Capucha, 2017;
145 Bergström, 2018; Schwartz, 2018). In the 1970s, the ecologist C.S. Holling (1973, p. 14) redefines
146 resilience as “a measure of the persistence of systems and their ability to absorb change and
147 disturbance.” Thus understood, resilience is widely conceived as the opposite of vulnerability, which is
148 defined as the inability to absorb change and disturbance (Gallopín, 2006; Miller et al., 2010). For
149 instance, a coastal system that is vulnerable to accelerated sea-level rise is not resilient enough (Smit,
150 Goosen and Hulsbergen, 1998). In such accounts, greater resilience means becoming less vulnerable
151 to change and shocks. That said, a system can still be vulnerable to other changes while being resilient
152 in other respects (Gallopín, 2006). Holling incorporates resilience in a socio-ecological systems (SES)
153 approach to analyze the stability and strength of ecological systems, which are constituted by the
154 interaction between natural ecosystems and human societies (Alexander, 2013; Bergström, 2018;
155 Béné et al., 2018; Hoekstra, Bredenhoff-Bijlsma and Krol, 2018). Ecosystems, as noted earlier, are
156 rarely closed systems, but are instead subjected to natural and human influences.

157 In the social sciences, resilience research has been influenced by these earlier studies. As a
158 result, some social scientists have recourse to mathematical and simulation models and consider
159 resilience as a property of a system, which can be (made) weak or strong. In these studies, society is
160 modelled as a social system that consists of parts (including agents and technologies) and physical
161 properties that can be objectively studied (Aiken, 2006; Floridi, 2017). Resilience as a system property
162 is an objective measure of the dynamic equilibrium, stability, strength, or survivability of a socio-

163 ecological system, including coastal systems, urban systems, forest systems, etc. (Hoekstra,
164 Bredenhoff-Bijlsma and Krol, 2018). Such approaches, indebted to applied natural sciences and the
165 complex systems theory, can be very useful, especially when both the problem and the solution are
166 primarily and solely of a technical nature. That said, even an apparently purely technical process such
167 as water purification involves reckoning with various social factors (for instance, changing habits,
168 medicine uses and particular surroundings of water collection systems).

169 The story becomes even more complicated when, for instance, attempts to make communities
170 more resilient to climate change overlook the political and cultural reasons why particular groups living
171 in particular areas are more vulnerable to the effects of climate change (such as ~~tsunami, hurricane,~~
172 heavy rainfall, ~~drought~~droughts, and heatwaves). These problems may not even get sufficient
173 attention due to, for instance, “cultural racism and “institutional racism” (Henkel et al., 2006, p. 102).
174 Social constructivism provides social scientists with the conceptual and analytical tools to understand
175 social realities. Historically, constructivism in the social sciences ~~has arisen~~arose in reaction to what
176 was experienced as the narrowness of the naturalist approach (once again, in the technical/strict sense
177 of the term, according to which “the social is part of nature, social processes are natural processes,
178 with causal powers reducible to natural causation” ~~{(Andler, 2014, p. 286)}-}).~~ Most social
179 constructivists do not believe that reality is objective in the naturalist sense (strictly defined) and ~~can~~
180 thus cannot be fully grasped. Instead, it is conceived that natural and social phenomena can only
181 understood by taking into account diverse factors that determine and influence ~~-~~human perceptions,
182 experiences, meanings, interests, values, identities, patterns of domination, etc.

183 In resilience research, social constructivists typically model society as a historically embedded
184 construct that is the result of particular understandings of nature, society, and the person, of values,
185 symbols and historical practices (which may not be very rational or just), and power relations. These
186 social scientists tend to be more sensitive to the potential and actual abuse of power. When ~~-~~engaging
187 with resilience issues in the context of climate change, they typically express concern for vulnerable
188 communities. Research topics can thus include the (un)equal distribution of environmental burdens,

189 struggles for recognition, claims to participation, and unequal impacts of anthropogenic climate
190 change (Braun, 2014; Yanarella and Levine, 2014; Skillington, 2015; Sjöstedt, 2015; Weichselgartner
191 and Kelman, 2015; Pizzo, 2015; Lockie, 2016; Derickson, 2016; Lyster, 2017; Schlosberg, Collins, and
192 Niemeyer, 2017; Mummery and Mummery, 2019). Davoudi (2018, p. 5), for instance, problematize the
193 very notion of “resilience”, pointing out that there are “unjust resilience building programs” that do
194 not only neglect disadvantaged communities, but also create “resilient enclaves” for privileged elites”.
195 Similarly, Glaser et al (2018, p. 3) observe that resilience can be “wicked” when an undesirable status
196 quo is being maintained. Reflexivity is arguably an indispensable part of resilience research (cf. Popa
197 et al., 2015).

198

199

200 **2.1. The dialectic between naturalism and constructivism**

201

202 Social scientists focusing on resilience to climate change have inherited an enormous body of
203 scholarship on resilience stemming from the physical sciences and engineering, cybernetics,
204 evolutionary biology, and psychology, among others. In the 1970s, social scientists could thus have
205 recourse to both closed-systems theories and complexity theory to think about resilience to climate
206 change (Dahlberg, 2015; Davoudi, 2018). Some of them also merged the two models so that socio-
207 ecological systems became conceptualized as adaptive complex systems (Wiese, 2016; Bergström,
208 2018). Holling’s SES is an example of the integration of complexity theory in ecological science.
209 According to the adaptive complex system line of thought, the resilience of a system depends on the
210 capacity of individual agents to cope with uncertainty and complexity. They are able to interact and
211 self-organize, learn, and adapt (in an incremental or transformative way), thereby making the system
212 flexible enough to absorb shocks and develop even in face of drastic changes (Jesse, Heinrichs and
213 Kuchshinrichs, 2019).

214 Social scientists drawing on complexity theory and evolution-based models tend to emphasize
215 a type of laissez-faireism, pointing out that adaptive complex systems have their own self-
216 organizational structures that should not be interfered with (Adger et al., 2011). Bureaucratic
217 interventions to address vulnerability and increase resilience to climate change are said to generate
218 unintended consequences that may well reduce a system's ability to absorb changes and disturbances.
219 In 2001, Holling introduced the notion of "panarchy" as an alternative to hierarchy, to safeguard the
220 self-organization of complex systems against the threat of bureaucratic intervention (Holling, 2001).
221 Derived from the ancient Greek god of the woods, Pan, panarchy refers to the structure in which
222 complex (ecological and social) systems are interlinked in an evolutionary process of adaptive cycles
223 of growth, accumulation, restructuring, and renewal (Berkes and Ross, 2016). Accordingly, when
224 confronted with shocks (like extreme weather events), adaptive systems stabilize with supporting self-
225 organizing structures until those structures are overstretched and can no longer absorb changes and
226 disturbances; this is when there is a transformation of the system (Allen et al., 2014). Resilience is
227 therefore conceived as a primary system property that is measured by the magnitude of shocks that
228 can be absorbed before the structures of system change (Boyer, 2020).

229 Some social scientists show a predilection for agent-based modelling (ABM) as their mode of
230 analysis in resilience research (cf. Cote and Nightingale, 2012; Pumpuni-Lens, Blackburn and
231 Garstenauer, 2017; Patriarca et al., 2018; Mirchandani, 2020). They therefore aim at the constant
232 refinement of simulation tools that can integrate complexity, uncertainty and multiplicity of agents
233 and techniques of regulation in favor of adaptation. Since the 1970s, when it emerged from
234 mathematical sociology, ABM has been used in complexity-theoretic research for analyzing complex
235 systems (Conte and Paolucci, 2014). ABM is a computational mode of analysis that simulates complex
236 (non-linear) systems that include diverse interacting agents that make decisions, interact, and learn or
237 adapt in their ever-changing environment, according to programmable rules (Hawes and Reed, 2006;
238 Farmer and Foley, 2009; Van Duinen et al., 2015; Martin and Schlüter, 2015; Sun, Stojadinovic and
239 Sansavini, 2019). ABM computes, in probabilistic terms, the recovery process of complex (non-linear)

240 systems under stress and tracks the emergence of new stages, phases or entries into new adaptive
241 cycles (Filatova, Polhill and Van Ewijk, 2016). Resilience to climate change, as a system property, can
242 thus be calculated (Pumpuni-Lenss, Blackburn and Garstenauer, 2017). Since ABM traces feedbacks
243 between micro- and macro scale explicitly, it also enables scholars to- estimate the resilience of a
244 system's individual agents, communities or (sub)groups of agents.

245 The above- approaches to resilience rely on what can be broadly defined as "natural" sciences
246 and their applied variants. Society and human persons are conceived according to the theories and
247 models common in these disciplines. The application of conceptual frameworks and models developed
248 to study allegedly objective and objectifiable things to the interaction between humans and their social
249 and natural environments is not without its challenges and dangers. Scientists, including social
250 scientists, may unwittingly serve political agendas if they are oblivious of their own political and
251 ideological commitments (Popa et al., 2014). The blurry line between science and politics is illustrated
252 by Holling's and Friedrich Hayek's re-appropriation of complexity theory to criticize government
253 ~~intervention~~interventions (Walker and Cooper, 2011; Davoudi, 2018). The historical context of both
254 men, namely, one marked by Keynesian policies, should arguably also be borne in mind. One of the
255 possible (side)effects of scientific models presuming resilient individual agents is that they can lend
256 credence to the idea of self-reliant and self-sufficient individuals and further the "neoliberal
257 individualization of responsibility" (Davoudi, 2018, p. 5). Such alliance, perhaps unwitting, between
258 political agendas and science is the great fear of those social constructivists whose primary
259 commitment is to justice and the protection of vulnerable individuals and groups (Fainstein, 2014;
260 Derickson, 2016; Kolars, 2016; Lockie, 2016; Lyster, 2017; Mummery and Mummery, 2019).

261 One of the major points of contention between naturalism, in the strict sense, and social
262 constructivism is that most social constructivists are unwilling to conceive resilience to climate change
263 as a system property (an intellectual attitude that -does not imply -that all naturalistic approaches
264 actually conceive resilience as a system property)-cf. Andler, 2014). Instead, resilience is perceived
265 as a socio-political construct created by diverse stakeholders (Walsh-Dilley and Wolford, 2015;

Formatted: Font color: Text 1

266 Weichselgartner and Kelman, 2015; Kythreotis and Bristow, 2017). This means that it is not a neutral
267 or technical element and, accordingly, requires constant critical scrutiny to uncover its possible
268 ideological and mythical nature (Alexander, 2013; Bourbeau, 2015; Boas and Rothe, 2016; Juncos,
269 2018; Wessel, 2019). Some scholars have pointed out the neoliberal ideology underpinning both
270 theories/models and policies that rely on the idea of adaptive cycles governed by invisible laws, which
271 make intervention undesirable (Chandler, 2014; Tierney, 2015). It is thereby overlooked that the so-
272 called self-organizing system is itself the result of political decisions over a long period of time.
273 Governments are thus accused of shifting the responsibility for vulnerable systems (which are
274 themselves the products of formal and informal institutions and political decisions, among other
275 things), floods, pollution, safety, welfare, health, etc. onto “resilient” individuals or individuals who
276 ought to be become more resilient, which is another word for self-reliant (Braun, 2014; Pizzo, 2015;
277 Tierney, 2015; Howell, 2015; Anderson, 2015; Ksenia et al., 2016; Schwartz, 2018; Davoudi, 2018). In
278 some cases, such resilience discourse enables governments to avoid their public responsibility. An
279 instance of such “wicked” dynamics is ~~governments~~“governments’ shifting the responsibility for the
280 provision of access to water onto local “communities” while the latter might be absent due to strife or
281 inadequate management capacities (Katomero and Georgiadou, 2018). In such situations, vulnerable
282 individuals and groups are denied this basic human right, while other powerful groups claim sole access
283 to water.

284 Social constructivists are generally critical of the very language of resilience. Those who point
285 out the discursive or narrative nature of resilience-based political speeches and policies are usually
286 indebted to Michel Foucault’s idea of a discourse. The latter refers to systems of thoughts and beliefs
287 expressed through language and practices that systematically construct subjects and societies of which
288 they speak. In other words, both language and practices are creative acts. Through resilience
289 discourses, a particular type of subject (like resilient or self-reliant) and a particular type of society (like
290 a market-based “society”) are discursively constructed and reinforced (Miller et al., 2010). Evans and
291 Reid (2013) thus argue that resilience has the character of a doctrine, according to which the resilient

292 subject must accept and constantly adapt to a dangerous and changing world. Given this doctrine,
293 vulnerability is rejected as weakness, or a moral flaw ~~–~~, which is very much like a lack of character or
294 will power ~~–~~ (Cole, 2016). A problematic normativity is brought into existence when citizens are
295 expected to adapt to ecological and societal catastrophes by becoming self-reliant (Fainstein, 2014;
296 Tierney, 2015; Kolers, 2016; Ribault, 2019). In other words, some (or most) social constructivists do
297 not merely try to answer the question of how to make societies and individuals resilient to climate
298 change, but instead question the normativity of the concept “resilience”. Such a critical approach is
299 arguably problematic and counterproductive in some cases. The urgency of real problems (like rising
300 watersea levels that threaten millions of people) makes a dialogue between different approaches
301 highly desirable.

302

303

304 **3. Bridging the naturalist and constructivist view on resilience**

305

306 Given the different appraisals of the very concept of resilience with respect to climate change among
307 social scientists, it has been widely questioned whether resilience can possibly operate as a theoretical
308 model or a unifying paradigm – and whether such a unifying paradigm would be desirable in the first
309 place (Alexander, 2013; Thorén, 2014; Bourbeau, 2015; Fainstein, 2015; Pizzo, 2015). -The question of
310 whether such unifying paradigm is possible or desirable need not be answered here. It can still be
311 argued that it is desirable to bring together the insights gained from naturalistic and constructivist
312 approaches to enrich and renew understandings of resilience to climate change. ~~Resilience to~~
313 ~~climate~~Climate change resilience research that relies on naturalist and naturalistic premises may be
314 able to provide quick solutions to crises precisely because various unpredictable and apparently
315 irrelevant elements are discounted. The focus on the obvious problem without taking into account the
316 broader context – which may be problematic – has many advantages, certainly if the bigger picture is
317 taken into account after recovery from an acute crisis. In the event of a flood, for instance, the first

318 concerns should arguably be evacuation and preventing another flood. Once everyone is safe, the
319 question as to why the flood has affected a particular group can be raised. The particular choices made
320 with regard to urban and rural planning can be critically scrutinized. Answers to the various questions
321 that a flood and its aftermath raise will require knowledge from many disciplines. “Resilience” to floods
322 will mean much more than building dams. It will also involve criticism of particular social structures,
323 institutions and decisions that have rendered some people or areas more vulnerable to natural hazards
324 or the effects of climate change.

325

326

327

328 **3.1 The debate on adaptive and transformative resilience**

329

330 Resilience research in recent years reveals divergence ~~between~~among social scientists when it comes
331 to the issue of adaptation and transformation (Chandler, 2014; Redman, 2014; Fainstein, 2014;
332 Dahlberg et al., 2015; Sjöstedt, 2015; Boas and Rothe, 2016; Duit, 2016; Ziervogel, Cowen and Ziniades,
333 2016; Clément and Rivera, 2017; Lyster, 2017; Schlosberg, Collins and Niemeyer, 2017; Fazey et al.,
334 2018; Glaser et al., 2018; Hoekstra, Bredenhoff-Bijlsma and Krol, 2018; Jesse, Heinrichs and
335 Kuchshinrichs, 2019; Dryzek and Pickering, 2019). Such disagreement can partly be explained by a
336 particular ambiguity in Holling’s SES approach (Redman, 2014). In the 1970s, Holling (1973)
337 reinterpreted resilience as bouncing back or forward in terms of SES adaptation. Adaptation refers, on
338 the one hand, to the capacity of agents to influence the system (and influence or strengthen resilience
339 as a system property). And on the other hand, it alludes to panarchical adaptation to new (ecological
340 and social) environments, as an evolutionary process towards a new stage, phase, or adaptation cycle
341 (Boyd et al., 2015).

342 Yet, as Holling emphasizes, the bouncing back and bouncing forward of a system not only refers
343 to a return to some previous (dynamic) equilibrium or to the persistence and endurance of systems. It

344 also refers to socio-ecological transformation in an ongoing process of non-equilibrium and instability
345 and reinvention of systems in changing environments marked by different adaptive cycles-~~}, such as~~
346 growth, accumulation, restructuring, and renewal~~}~~ (Folke, 2006). Transformation means that agents
347 are capable of creating a new system and a new discourse, particularly when the existing system is
348 untenable or illegitimate. This focus on undesirable status quos and hence on transformation – after a
349 crisis, for example – is characteristic of many social constructivists, but may also be important to those
350 who have somehow combined the goods of several worlds (Carolan, 2005; Code, 2005). Scholars
351 critical of resilience discourses propounded by national and international governance actors,
352 therefore, do not try to find ways to increase resilience, but above all things, try to ~~-~~ignite new
353 imaginations and counter-discourses necessary for realizing less unsustainable futures (Fazey et al.,
354 2018). Recently, a middle ground between adaptation and transformation has been developed, in the
355 form of “transformational adaptation” (Pelling, O’Brien and Matyas, 2015; Mummery and Mummery,
356 2019). Examples of transformational adaptations include green growth or the greening of ~~-~~present
357 economies.~~-~~ These are changes that are aligned with the scale of projected, possible and desirable
358 changes within systems that are informed by ~~-~~considerations of justice.

359 Resilience research that emphasizes system adaption to climate change focusses on the degree
360 to which complex systems can build capacity for learning, as a way to respond to shocks or
361 disturbances, embrace evolutionary change, and live with complexity and uncertainty (Thorén, 2014;
362 Juncos, 2017; Warmink et al., 2017; Béné et al., 2018). Given unpredictability and uncontrollability,
363 adaptive resilience is especially a matter of short-term planning, uncertainty reductions, incremental
364 and path-dependent changes (Borsje et al, 2011; Haasnoot et al., 2013). Adaptive resilience – the
365 system’s re-stabilizer – is conceived as inherently positive, while disturbances and shocks (de-
366 stabilizers) are ~~-~~negative (Duit, 2016; Lockie, 2016). Research building on the premise that adaptive
367 resilience is desirable thus partners well with climate risk management (Boyd et al., 2015; Berbés-
368 Blázquez et al., 2017). The response of the Dutch government to the overflowing of the Meuse River
369 in 1993 and 1995 illustrates research-based risk reduction through adaption that involves a break with

370 the past. The Dutch government did not simply have recourse to building more dikesdykes and
371 strengthening existing barriers, which has been the traditional approach, but instead opted for river
372 deepening and widening measures (Dijkman et al., 1997; Hamers et al., 2015). Since its completion in
373 2015, the Room for the River project is considered effective thus far, particularly as its secondary
374 objective to increase ecosystem values in the river appears to be successful. However, a research
375 completed in 2013 (Ward et al., 2013) points out that the risk of flooding in certain parts of the
376 Netherlands is expected to increase in the future (two- to three-fold increase by 2030 compared to
377 2010), and emphasizes the need for change at the level of with respect to land-use. Indeed, the
378 researchers found out that the impact of land-use on flood risk is likely to be greater than climate
379 change itself. This means that households, for instance, can help to reduce the risk of future floods
380 through a change of behavior. But that's that is easier said than done. The authors of the report note
381 that there are few means to move Dutch households to participate in such risk reduction and point out
382 the need for further research on ways to implement new measures and motivate people to change
383 their behavior (Ward et al., 2013: 45).

384 Research that prioritizes transformative resilience in the context of climate change looks at a
385 system's internal capacities, capabilities and relations that enable it to create a new condition marked
386 by new or different power relationships and different priorities. In such cases, constructivists typically
387 point out the undesirability and injustice of status quos (Ziervogel, Cowen and Ziniades, 2016; Rothe,
388 2017; Béné et al., 2018). According to this perspective, "anthropological shocks" (Beck, 2015, 80) open
389 up new horizons, reassessments (including of past ideas, beliefs, and practices) and rediscoveries
390 (Beck, 2015; Fazey et al., 2018). "Anthropological shocks" refer to the disruptive and lasting effects of
391 certain horrendous events on people. There is no going back to how it was before these shocks.
392 According to these critical voices, adaptive resilience research and policies based on that research
393 contribute to maintaining systems that are unjust (Skillington, 2015; Derickson, 2016; Fazey et al.,
394 2018; Mummery and Mummery, 2019). This does not mean that adaptive resilience research – which
395 usually draws on "naturalistic" methods – does not include justice in its models (Redman, 2014;

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

396 Thorén, 2014; Ksenia et al., 2016; Schlosberg, Collins and Niemeyer, 2017; Bergström, 2018). Yet, such
397 models are based on, and reflects, existing systems. They ~~cannot do not~~ take structures of power into
398 account ~~because that structural power — to influence production, consumption, knowledge, and so on~~
399 ~~— is not a measurable entity~~ (Howell, 2015; Pizzo, 2015; Lockie, 2016; Derickson, 2016; Davoudi, 2018).
400 This also means that they cannot possibly integrate thoroughly unequal power relationships – such as
401 the Global North-Global South relationship – into their models ([Swyngedouw, 2011](#); Pizzo, 2015;
402 Clément and Rivera, 2017; Davoudi, 2018; Glaser et al., 2018; Dryzek and Pickering, 2019).

403 The limitations of models need not be a problem unless they become the political tools to
404 implement adaptive measures (Fainstein, 2014; Weichselgartner and Kelman, 2015; Huang, Boranbay-
405 Akan and Huang, 2016; McGreavy, 2016; Ziervogel, Cowen and Ziniades, 2016; Ribault, 2019).
406 Adaptive responses to shocks and disturbances may blur long-term sustainability visions and enable
407 powerful stakeholders to maintain their positions (Lockie, 2016; Derickson, 2016; Rothe, 2017;
408 Estêvão, Calado and Capucha, 2017; Ribault, 2019). Kythreotis and Bristow (2017) call this
409 phenomenon the “resilience trap” – the reinforcement of established power relations – and
410 contemporary resilience discourses (Blühdorn, 2013; Redman, 2014; Yanarella and Levine, 2014;
411 Lockie, 2016; VanderPlaat, 2016; Schilling, Wyss and Binder, 2018; Glaser et al., 2018; Ribault, 2019).
412 Hence, some constructivist scholars reject Holling’s panarchy concept, emphasizing that
413 transformation towards more sustainable worlds is not an evolutionary process of adaptive cycles but
414 a political-administrative phenomenon (cf. Boyer, 2020).

415

416

417

418 **3.2 Transformative resilience and sustainability**

419

420 For some constructivist scholars, genuine sustainability presupposes transformative resilience because
421 inherently unsustainable systems cannot be made more wholesome by tweaking a few of their

422 constituents. In cases of inherent or structural defects, resilience refers to the capacity to “use” a crisis
423 to reappraise critically the social, cultural, and political choices underpinning SES, and if necessary, to
424 make new choices (Pizzo, 2015; Weichselgartner and Kelman, 2015; VanderPlaat, 2016; Ziervogel,
425 Cowen and Ziniades, 2016; Hughes, 2017; Jesse, Heinrichs and Kuchshinrichs, 2019). The
426 reconfigurations of SES do require interventions by all governance actors. Transformative resilience
427 used in this sense is thus a post-neoliberal concept. –When applied to the energy transition,
428 transformative resilience entails a more radical change than adaptive resilience does. In the former
429 case, this means concrete plans to phase out fossil fuels and hence to reorganize economies, where
430 the old fossil fuel industry no longer holds the reins (Alexander and Yacoumis, 2018; Stegemann and
431 Ossewaarde, 2018; Bergmann and Ossewaarde, 2020). Adaptive resilience is involved when the
432 phasing out of fossil fuels is being delayed and when certain discourses ensure that the fossil industry
433 is given carte blanche to carry on business as usual (Buschmann and Oels, 2019). Geels (2014, p. 24)
434 explains how “the coal regime has so far resisted climate change pressures through a “clean coal”
435 discourse and the innovation promise of carbon capture and storage (CCS).”
436 It is widely agreed that non-renewable fossil energy sources like coal, oil and gas are largely responsible
437 for landscape degradation, air and water pollution, as well as greenhouse gas ~~emissions and other~~
438 ~~pollutants~~ that ~~have~~ been causing global warming (Cook et al., 2016). The sustainable energy
439 transformation, accordingly, is, amongst other things, a response to climate change. In a more robust
440 sense, it is more than simply a response to climate change. Instead, the latter is a symptom of the
441 inherent unsustainability of the present socioeconomic system and is therefore an additional, urgent
442 reason to radically transform the latter (Alexander and Yacoumis, 2018). Hence, those who conceive
443 an energy transition as an adaptive necessity are primarily concerned with what several scholars call
444 “energy resilience” (Béné et al., 2018, p. 120; Jesse, Heinrichs and Kuchshinrichs, 2019, p. 21), that is,
445 with the continuing supply of energy to support the prevailing socioeconomic system and prevention
446 of power outage during the transition.

Formatted: Font color: Custom Color(RGB(34;34;34))

447 In other words, reliable energy supplies at stable costs must be kept going to support the
448 present socioeconomic system t (Wiese, 2016). Since system collapse is to be avoided at any cost,
449 adaptive resilience to climate change means incremental changes and the increasing use of renewables
450 without stopping the use of fossil fuels (Berbés-Blázquez et al., 2017; Schilling, Wyss and Binder, 2018;
451 Stegemann and Ossewaarde, ~~2018~~). Adaptive resilience here means the gradual greening of energy
452 and hence the gradual greening of the system through green technological innovation without
453 essentially changing the old system (Geels, 2014). In fact, important stakeholders of the “old regime”
454 resist the transition to a new order (ibid). Such resistance takes, among other things, the form of
455 continuing investments in fossil-fuel-based energy and greening measures – which create the
456 impression of a transition (especially in the media) – thereby further anchoring the existing system
457 (Alova, 2020; Gençsü et al., 2020). The incentives to “destabilize” such a flourishing economic system
458 are thus weakened.

459 Scholars who challenge existing social structures therefore critically point out that the primary
460 and sole focus on “energy resilience” (that is to say, energy security) is more likely to maintain the
461 energy system’s status quo, which further allows powerful stakeholders to promote fossil energy and
462 keep their established positions. As Simpson (2013, p. 249) notes, the “critical approach to energy
463 security challenges the existing economic, political and technical assumptions that underpin traditional
464 debates on energy production and consumption, but it also challenges traditional notions of security
465 that have the nation-state as their referent object”. An uncritical adaptive energy resilience approach
466 can thus reinforce “energy injustice”, that is, the “the unequal distribution of ills” throughout the
467 energy system, whereby that system is defined as “the entire energy chain, from mining, conversion,
468 production, transmission, and distribution, right through to energy consumption and waste” (Jenkins
469 et al., 2016, p. 179). Scholars who focus on the transformative resilience of energy systems are
470 therefore generally committed to energy justice and have a more critical approach to energy resilience
471 (or security) because the latter presumes the -socioeconomic order and unequal structures of power
472 (Jenkins et al., 2016; Heffron and McCauley, 2017). They propose the creation of a renewable energy-

Formatted: No underline

473 based system, energy commons and collaboratives beyond the energy establishment (VanderPlaat,
474 2016; Bourbeau and Ryan, 2018; Juncos, 2018; Schwartz, 2018; Acosta et al., 2018; Jesse, Heinrichs
475 and Kuchshinrichs, 2019).

476

477

478 **4. Six ~~upcoming~~emerging themes in diversified resilience research**

479

480 Current research on resilience to climate change in the social sciences reflects a diversity of focusses
481 and commitments, ranging from climate-resilient infrastructure to issues of justice and power. Some
482 critical scholars question the very notion of resilience and point to the “wicked” dynamics involved as
483 “resilience” becomes a policy instrument to consolidate one particular, often established social reality
484 at the expense of other, fairer possible alternatives. Research that unwittingly supports such political
485 purpose has thus attracted the criticism of scholars who emphasize transformation towards new social
486 constellations, where power (to influence the course of things), responsibility, burdens, and benefits
487 are fairly distributed (Derickson, 2016; Jenkins et al., 2016; Heffron and McCauley, 2017; Alexander
488 and Yacoumis, 2018; Davoudi, 2018; Glaser et al., 2018; Stegemann and Ossewaarde, 2018).
489 Ultimately, the overarching challenge for future research is to ensure that resilience to climate change
490 does not compromise sustainability and considerations of justice (including, environmental, climate
491 and energy justice). Based on our overview of recent scholarship, which cannot possibly be exhaustive,
492 we have identified six research avenues that deserve ~~continuing~~continued attention.

493 One of them is the further development of transdisciplinarity, which includes the collaboration
494 between constructivist and naturalistic approaches to resilience, not only at the institutional level, but
495 especially at the level of research itself. Such transdisciplinarity thus means that a scholar draws on
496 different scientific traditions to approach one particular problem. In other words, transdisciplinarity
497 does not restrict itself to “forced” collaboration between scholars from different disciplines, which is
498 a prevalent organization of inter-, multi- and trans -disciplinarity (cf. Pohl, 2001). It also does not mean

499 homogenization of science and the repression of the diversity of human thinking. It ~~does entail~~ entails
500 an appreciation of diverse scientific vocabularies, of the variety of scientific knowledge, and the
501 acknowledgement of clashes, which can be conducive to the advancement of human knowledge (cf.
502 Pfeffer and Georgiadou, 2019). Bringing together various perspectives of a complex reality arguably
503 fosters our understanding of that same reality.

504 There have been several attempts to “bridge” the disciplinary divide, some more successful than
505 others. Such attempts at integration are deemed even more desirable when it comes to environmental
506 issues (Pompe and Rinehart, 2002; Mooney et al., 2013). Edward O. ~~Wilson~~ Wilson’s famous “consilience”
507 is a good example of a failed attempt since he takes the natural sciences and their methods to be hegemonic.
508 Wilson (1998, p. 11) thus notes:

509
510 Given that human action comprises events of physical causation, why should the social
511 sciences and humanities be impervious to consilience with the natural sciences? [...] Nothing
512 fundamental separates the course of human history from the course of physical history,
513 whether in the stars or in organic diversity.

514
515 Similarly, the allegedly transdisciplinary “Earth System Analysis” approach, developed at the Potsdam-
516 Institute for Climate Impact Research (Germany), makes use of mathematical modelling in which the
517 world is conceived as a cybernetic organism (Pohl, 2001, p. 40).

518 More successful integrative approaches do not allow the methodology and theoretical framework
519 of one particular scientific tradition to dominate the other. We have mentioned “ecological naturalism”
520 above as an example of such an approach. The “critical realist” (Proctor, 1998) is yet another way to
521 benefit from the realism of the naturalist approach, thereby avoiding relativism, without falling into
522 the trap of reification and determinism. With regard to energy, for instance, Jenkins et al (2016, p. 179)
523 argue that a “combination of the social science account of energy (policy) with its natural science
524 counterpart (systems)” helps us to determine where injustices lie, even more accurately than through

525 social constructivist approaches alone. Conversely, evolutionary resilience approaches that draw on
526 ~~systems~~ thinking can be enriched by taking into account human agency, the issue “unequal
527 power relations that can disrupt feedback loops and channels of communications” (Davoudi, 2018, p.
528 4), and more generally, the idea that we cannot simply wait for evolutionary change, or for systems to
529 explode, but instead have to realize alternatives ~~imagined by~~ human imagination.

530 This brings us to the second theme, which could be dubbed “critical resilience” research.
531 Critical thinking is arguably a precondition for, and characteristic of, science in general. This means that
532 reservations with regard to the very concept “resilience”, in policies and models, need to be taken
533 seriously. Research that constantly analyses the dominant and new – and often, implicit – conceptions
534 of resilience must thus be stimulated even if it does not seem to serve practical purposes. Critical
535 resilience research thus also includes the integration of reflexivity in transdisciplinary research, which
536 involves “a reflexive questioning of values, background assumptions and normative orientations”
537 (Popa et al., 2015, p. 46) of various approaches to resilience. Critical resilience research is expected to
538 pay attention to diverse conceptions of resilience and also to address the “question of outcomes and
539 who gets to define them as resilient or otherwise”, “the potential exclusions in determining system
540 ~~boundaries~~”, and “the question of the political—resilience from what, to what, and who
541 gets to decide?” (Porter and Davoudi, 2012, p. 331). Such critical resilience research can accompany
542 other resilience research, thereby preventing science from serving ideological goals.

543 A third research avenue, somewhat related to the second theme, consists in the
544 contextualization of resilience research and discourse, that is, in embedding ~~it~~ in ~~its~~ political
545 and cultural context. By understanding the bigger picture in which both the ecological crisis and the
546 responses to it arise, it may be possible to govern resilience research towards sustainability and justice,
547 and to identify the factors – which may be institutional, cultural or political – that stimulate or deter
548 such ~~change~~ (cf. Bahadur and Tanner, 2014). In a ~~systems~~ thinking language, such
549 research can ~~identify~~ the various agents that maintain or disrupt the system. ~~For instance, on~~
550 ~~the one hand,~~ An example of disruptive forces may then be environmental ~~protest~~ movements that are

Formatted: Pattern: Clear (White)

551 ~~stakeholders that able to~~ develop a leverage required to transform established systems (such as energy
552 systems) and their governance arrangements. ~~On~~Agents that maintain the system, on the other hand,
553 ~~agents include those~~ who hold power, thanks to such arrangements, and typically use tactics of
554 repression and criminalization, particularly in the extractive sectors of the Global South (Szablowski
555 and Campbell, 2019). Research focusing on the different fields of forces in various political contexts
556 may discover how differences in system adaptation and reconfiguration relate to particular
557 administrative capacities and governance arrangements (cf. Blühdorn, 2013; Fischer, 2017; Davoudi,
558 2018; Köhler et al., 2019; Mummery and Mummery, 2019). It can also generate insights into the
559 (possible) connection between particular resilience policies and models, on the one hand, and new
560 forms of power inequalities, polarization, injustice, and democratic deficits, on the other hand. and
561 Bierbaum and Stults (2013, p. 18) point to the “growing recognition of the need for a new model of
562 deep and long-term stakeholder engagement”. Such a model ~~ensure~~ensures that all (local)
563 stakeholders are involved in determining a “vision of resilience, impediments to achieving that vision,
564 and contextually relevant actions for achieving that vision” (Bierbaum and Stults, 2013, p. 30). It can
565 safeguard both the effectiveness and equitability of solutions.

566 A fourth promising topic for future resilience research is the interplay between adaptive
567 resilience and transformative resilience and transformational adaptation (Clément and Rivera, 2017).
568 The focus can be on the ways in which transformational adaptation manifests itself, how multiple
569 adaptations may lead to transformational adaptation and ~~the tipping point~~threshold that needs to
570 be surpassed for ~~igniting transformation~~adaptation to be considered as transformational (Grove and
571 Chandler, 2017; Glaser et al., 2018). The notion of “tentative governance” appears particularly relevant
572 in the context of transformational politics, when it comes to phasing out systems and weakening
573 adaptive resilience. Tentative governance is marked by interventions that are designed as preliminary
574 rather than as persistent, for purposes of probing and learning rather than for stipulating definite
575 targets or fixating existing systems and their underlying assumptions (Kuhlmann, Stegmaier and
576 Konrad, 2019). It is likely that stakeholder engagement (including resistance) in transformational

Formatted: Font color: Black

577 politics and tentative governance varies, and manifests itself differently, across different policy fields.
578 For instance, the sustainable energy transformation may include multi-layer governance challenges,
579 many pro-active stakeholders, new investment opportunities and job opportunities. In contrast with
580 the sustainable energy transformation, sea level rise and the disruption and relocation of coastal cities
581 may trigger a more limited transformative politics, despite inevitable transformation of systems due
582 to shocks and disturbances (metamorphosis). Yet, in the coming decade, transformational politics and
583 tentative governance – including anthropogenic topics like population displacement, privatization of
584 climate adaptation, conflict ~~organized around~~surrounding scarce resources (like water resources),
585 intergenerational environmental conflict, and the ~~closingshutting down~~ of old infrastructures that are
586 too costly to maintain – ~~becomes a~~become more urgent research ~~topic~~topics.

587 The fifth research theme concerns the relationship between the phasing out of unsustainable
588 systems and societal transformations. ~~In other words, what~~What are the implications of the
589 disintegration of old systems for societies, that is, for their cultures, collective identities, traditions,
590 economies, political-administrative power constellations, class structures, etc.~~?~~ and which? Which
591 societal transformations promote such disintegration? Research topics encompass the governing and
592 accelerating of the decline of existing systems and their adaptive cycles (Stegmaier, Visser and
593 Kuhlmann, 2014; Hoffmann, Weyer and Longen, 2017; Stegmaier, Visser and Kuhlmann, 2020); the
594 particular circumstances in which accelerations can manifest themselves; the identification of, and
595 coping with, uncertainties in processes of adaptation and transformation and transformational
596 adaptation; and the construction of new incentive structures, for accelerating sustainable
597 transformation (cf. Clément and Rivera, 2017; Warmink et al., 2017; Köhler et al., 2019). This branch
598 of discontinuation research assumes that technologies influence socio-ecological systems. Some
599 technologies threaten resilience to climate change, while others enhance it (Smith and Stirling 2010),
600 which brings us to another, related research topic, namely, the implications of the so-called “AI
601 Revolution” and the (top down and politically steered) making of the alleged “Age of Artificial
602 Intelligence” for resilience research and SES (Berendt, 2019).

Formatted: Font color: Black

603 Given worldwide investments in AI technologies and top-down AI strategies that global
604 governance actors and national governments have recently published (Ossewaarde and Gülenç,
605 2020), AI will most plausibly become a major force that shapes or undermines resilience to climate
606 change. New interplays between automation, (un)sustainability, and adapting and transforming
607 systems trigger new questions for future resilience research (cf. Köhler et al., 2019). Hoefsloot et al
608 (2019) have expressed the concern that the total and unconditional reliance on the data generated by
609 AI technology may lead to a flawed prediction of climate disasters. For instance, the coverage of
610 climate disasters – satellite data, drone data, sensor data, social media data, volunteer geographic
611 information (VGI) data, among others – may be incomplete and leave out certain geographical areas
612 and even certain social groups (Hoefsloot et al., 2019). Other sources of information are necessary to
613 ensure more accurate measurements (and predictions), complement data gaps and identify the needs
614 of local communities (Bierbaum and Stults, 2013; Pfeffer and Georgiadou 2019). A recent example of
615 the integration of different sources of knowledge is the resilient settlement program led by UN
616 HABITAT, which brought together a multitude of actors (policy, private, academic, community
617 organizations) and data and algorithms and local knowledges to identify settlements at risks
618 (unhabitat.orgUN-Habitat, 2019). This example illustrates the importance of embedding AI
619 technologies in particular contexts so that the needs of particular communities, for instance, are
620 served, and fairness and transparency are safeguarded. Resilience research and models must therefore
621 include an evaluation of AI technologies: ~~how~~. How has data been acquired and by whom?; ~~what?~~
622 What are the implications of particular AI technologies for the SES in question?; ~~which?~~ Which new
623 power relations are established through the reliance on AI technologies?; ~~which?~~ Which stakeholders
624 are being included and which ones are being excluded during the whole process, beginning with the
625 problem definition to the formulation of solutions that involve an intensive application of AI? (Rajan
626 and Saffiotti, 2017; Taddeo and Floridi, 2018; Khakurel et al., 2018; Vahedifard, et al., 2019; Miller,
627 2019; Saravi et al., 2019).

628 A sixth theme for future resilience research concerns the role of environmental, energy and
629 climate justice in theorizing, modeling, interpreting, and explaining resilience to climate change (cf.
630 Skillington, 2015; Fazey et al., 2018; Mummery and Mummery, 2019). What kind of research results
631 from the integration of theories of environmental justice, energy justice and climate justice into
632 adaptive and transformative resilience and transformational adaptation models? Future resilience
633 research will somehow have to confront wicked problems: given unstable political contexts, scarcity
634 of “resources” and struggles for survival and power, how can principles of equity, fairness and access
635 to resources and services be secured? In the problematic context of climate-induced
636 migration/mobilities and a political environment marked by anti-immigration policies, how can the
637 wellbeing of migrants be ensured and, in general, human rights be safeguarded? how? How can the
638 disparity and inequality in the distribution of risks, locally and globally, be tackled? Equity in this regard
639 will mean much more than equality. Other challenges include the incorporation of cross-sectional
640 dimensions of justice, particularly gender and racial/ethnic relations, into climate justice (Terry, 2009),
641 and energy justice (Feenstra and Özerol, 2018) frameworks. And in the Global South, addressing issues
642 of corruption, violence, poverty and lack of access to resources (and violent battles for resources) and
643 services (like education and sanitation) may have a higher priority than global environmental
644 considerations (Köhler et al., 2019).

645

646 5. Conclusion

647

648 In the social sciences, resilience to climate change is a concept that is incorporated in different
649 theoretical approaches that are linked to contrasting scientific approaches. Holling originally
650 reinterpreted and incorporated the notion of resilience in his SES approach, which was then picked up
651 by naturalist scientists and embedded in cybernetic complexity theory, for instance. The complexity
652 theory was for a very long time the preferred approach to resilience to climate change in the social
653 sciences. This situation changed as resilience increasingly became the theme of political discourses

654 and policies ~~some~~ decade ago, especially in the wake of socio-ecological catastrophes, financial crises,
655 and pandemics. –The instrumentalization and decontextualization of resilience by local and global
656 governance actors invited the critical response of scholars who often had recourse to constructivist
657 approached. The diversification of resilience research and expansion of the social scientific jargon
658 resulted from this development. The question of whether resilience should operate as a unifying
659 paradigm is not yet settled. However, it may well facilitate interdisciplinary dialogue and even
660 transdisciplinarity. Such cooperation or dialogue is arguably necessary given the extremely complex
661 nature of our socio-ecological predicaments. New light may be shed on how new political-
662 administrative institutions (including panarchical self-organization) and practices can respond in
663 legitimate ways (taking justice and vulnerability considerations into account) to the challenges of
664 ~~addressing~~ climate change ~~impacts~~, in different ecological, political and technological contexts (cf.
665 Johnsson et al., 2018). ▲

666 The six themes for future resilience research that we have identified combine naturalist and
667 constructivist insights and approaches so that human agency, reflexivity and considerations of justice
668 and equity are incorporated into research that predominantly involves ~~system~~~~systems~~ thinking. In fact,
669 further cooperation is the first identified research theme. Interdisciplinary and multidisciplinary
670 between naturalist and constructivist approaches and the many varieties of these approaches can
671 prove to be challenging, not only because of clashing methodologies and conceptual frameworks, but
672 also because of institutional factors. Yet, there have been attempts to reduce the gap between these
673 approaches, without ~~destroying~~~~eliminating~~ a fruitful tension. The second research area could be called
674 “critical resilience” research. It includes questioning the very concept of resilience and proposing
675 alternatives or supplementary concepts. Such critical resilience research will most probably be a
676 complement to, or necessary component of, other resilience research. The third theme consists in the
677 contextualization of resilience research, which serves the multiple purposes of effectiveness (of
678 measures), sustainability and justice. The interaction ~~between~~, as well as the blurry line, between
679 adaption (adaptive resilience) and transformation (transformative resilience) is the fourth research

Formatted: Pattern: Clear

680 area. -Related to the latter topic is research focusing on the two-way relationship between the phasing
681 out of unsustainable systems and societal transformations. Given the increasing incorporation of AI
682 technologies in resilience research and policies, a fifth research topic pertains to the implications of AI
683 technologies for societies, and more specifically, for sustainability and justice. The final theme is the
684 integration of various forms of justice (such as inter-racial) and theories of justice into resilience
685 research. We believe that the multifariousness of climate change resilience research is inevitable and
686 also desirable given the complexity of the issues under consideration. Whether such diversity is
687 maintained will depend on external factors, such as the preferences of research institutes (and
688 governments) and the availability of funding for all lines of research.
