**Abstract.** Analyses of future agricultural drought impacts require a multidisciplinary approach in which both human and environmental dynamics are studied. In this study, we ~~applied-used~~ the socio-hydrologic, agent-based drought risk adaptation model ADOPT. ~~This -model simulates the decisions of smallholder farmers regarding on-farm drought adaptation measures, and the resulting dynamics in household vulnerability and drought impact over time. We applied ADOPT to assess the effect of four top-down disaster risk reduction interventions~~various top-down drought risk reduction interventions~~\_~~ on smallholder farmers' drought risk in the Kenyan drylands;~~:-~~ ~~Moreover, T~~he robustness of additional extension services, ex-ante rather than ex-post cash transfers, improved early warnings and lowered credit rates ~~these (non-)governmental interventions under different climate change scenarios~~-was evaluated under different climate change scenarios. ~~ADOPT simulates water management decisions of smallholder farmers, and evaluates household food insecurity, poverty and emergency aid needs due to drought disasters. Model dynamics were informed by extensive field surveys and interviews from which decision rules were distilled based on bounded-rational behaviour theories.~~

Model results suggest that extension services increase the adoption of low-cost, newer drought adaptation measures while credit schemes are useful for ~~cost-effective but expensive~~-measures with a high investment cost, and ex-ante cash transfers allow the least wealthy households to adopt low-cost well-known measures. Improved ~~e~~Early warning systems show more effective in climate scenarios with less frequent droughts. Combining all four interventions displays a mutually-reinforcing effect with a sharp increase in the adoption of on-farm drought adaptation measures resulting in reduced food insecurity, decreased poverty levels and drastically lower need for emergency aid, even under hotter and drier climate conditions. These nonlinear synergies indicate that a holistic perspective is needed to support smallholder resilience in the Kenyan drylands.

**Key words:** Agent-based modelling, drought disasters, risk reduction, adaptation measures, adaptive behaviour, smallholder farmers, drought adaptation, AquacropOS, ADOPT, ~~drought risk reduction~~risk assessment; Kenya, dryland agriculture

## 31 1 Introduction

32 Droughts, defined as below-normal meteorological or hydrological conditions, are a pressing threat to the food  
33 production in the drylands of Sub-Saharan Africa (Brown et al., 2011; Cervigni & Morris, 2016; UNDP et al.,  
34 2009). Over the last decades, increasing temperatures and erratic or inadequate rainfall have already intensified  
35 drought disasters (Khisa, 2017). ~~C~~Climate change, population growth and socio-economic development will lead  
36 to additional pressures on water ~~availability-resources~~ (Erenstein, Kassie, & Mwangi, 2011; Kitonyo et al., 2013).  
37 In Kenya, three quarters of the population depends on smallholder rain-fed agricultural production and nearly half  
38 of the population is annually exposed to ~~re-occurring~~recurring drought disasters causing income insecurity,  
39 malnutrition and health issues (Alessandro et al., 2015; Khisa, 2018; Mutunga et al., 2017; Rudari et al., 2019;  
40 UNDP, 2012). Reducing drought risk is imperative to enhance the resilience of the agriculture sector, to protect  
41 the livelihoods of the rural population, and to avoid food insecurity and famine in Kenya's drylands (Khisa, 2017;  
42 Shikuku et al., 2017).

43 Drought risk models are important tools to inform policy makers about the effectiveness of adaptation policies  
44 and enable the design of customized drought adaptation strategies under different future climate scenarios (Carrao  
45 et al., 2016; Stefano et al., 2015). Traditionally, such models express disaster risk as the product of hazard,  
46 exposure and vulnerability, and are based on historical risk data. Recent disaster risk models have dealt with  
47 climate change adaptation in a two-stage framework; first describing ~~a few scenarios regarding the~~adaptation  
48 choices of representative households, then estimating the impacts of adaptation on (future-) welfare while  
49 assuming climate change scenarios (di Falco, 2014). However, most existing research does not account for ~~more~~  
50 ~~complex dynamics in adaptation and~~ vulnerability ~~dynamics~~(Conway et al., 2019), ~~for~~ the heterogeneity in human  
51 adaptive behaviour (~~Schrieks et al 2021~~Aerts et al. 2018) ~~or, and for the feedback between risk dynamics and~~  
52 ~~adaptive behaviour dynamics its feedbacks on drought risk~~(Di Baldassarre et al., 2017). ~~Though, while it are~~  
53 ~~these these are the~~ aspects that determine, for a large part, the actual risk (Eiser et al., 2012).

54 ~~Uncertainties in adaptive behaviour are often addressed by using different adaptation scenarios, but this approach~~  
55 ~~fails to capture the two-way interaction between risk dynamics and adaptive behaviour dynamics (Elshafei, 2016).~~

56 It appears that farmers often act ~~boundedly~~ rational towards drought adaptation rather than economically rational:  
57 their ~~economic~~ rationality ~~isn limited-bounded~~ in terms of cognitive capability, information available, perceptions,  
58 heuristics and biases (Schrieks et al., 2021; Wens et al., 2021). To account for such individual adaptive behaviour  
59 ~~in drought risk assessments~~, an agent-based modelling technique can be applied (Berger & Troost, 2014; Blair &  
60 Buytaert, 2016; Filatova et al., 2013; Kelly et al., 2013; Matthews et al., 2007; Smajgl et al., 2011; Smajgl &  
61 Barreteau, 2017). Agent-based models allow explicitly simulation of the bottom-up individual human adaptation  
62 ~~decisions, and~~decisions and capture the macro-scale consequences that emerge from the ~~interventions-interactions~~  
63 between individual agents and their environments. Combining risk models with an agent-based approach is thus  
64 a promising way to analyse drought risk, and the evolution of it through time, in a more realistic way (Wens et  
65 al., 2019).

66 Here we present how an ~~n innovative dynamic-agent-based~~ drought risk adaptation model, ADOPT (~~designed in~~  
67 ~~Wens et al 2020~~), can increase our understanding of the effect of drought policies on community-scale drought

68 risk for smallholder farmers in Kenya's drylands. ~~ADOPT combines drought risk and agent based modelling~~  
69 ~~approaches by coupling the FAO crop model AquaCropOS with a decision making model, which is parameterized~~  
70 ~~following the Protection Motivation theory (PMT). The design of ADOPT as an agent-based drought risk~~  
71 ~~adaptation model is described in Wens et al., 2020. Moreover, Wens et al. (2021) detail the empirical data on past~~  
72 ~~adaptive behaviour (used to calibrate the model), as well as empirical data on adaptation intentions that can be~~  
73 ~~used to compare with the model outputs.~~

74 In this study, we apply the ADOPT model, to test the variation in household drought risk under different drought  
75 management policies: (i) a reactive government only providing emergency aid, (ii) a pro-active government,  
76 which provides sufficient drought early warnings and supports ex-ante cash transfer in the face of droughts ~~and~~  
77 ~~sufficient drought early warnings~~, and (ii) a strategieprospective government that, in addition to early warnings  
78 and ex-ante transfers, supports-subsidises adaptation credit schemes and provides regular drought adaptation  
79 extension services to farmers. In addition, ~~future ADOPT is used to evaluate drought risk and~~ the robustness of  
80 these policies ~~are evaluated~~ under different climate change scenarios. ~~Moreover, (a) (a) We acknowledge that~~  
81 ADOPT should be subject to additional validation steps in order to more accurately and precisely predict future  
82 drought risk. Yet, in this study we elaborate the potential of this proof-of-concept model by showcasing the trends  
83 in drought risk under risk reduction interventions and climate change for a case study in semi-arid Kenya.

## 84 2 Case study description

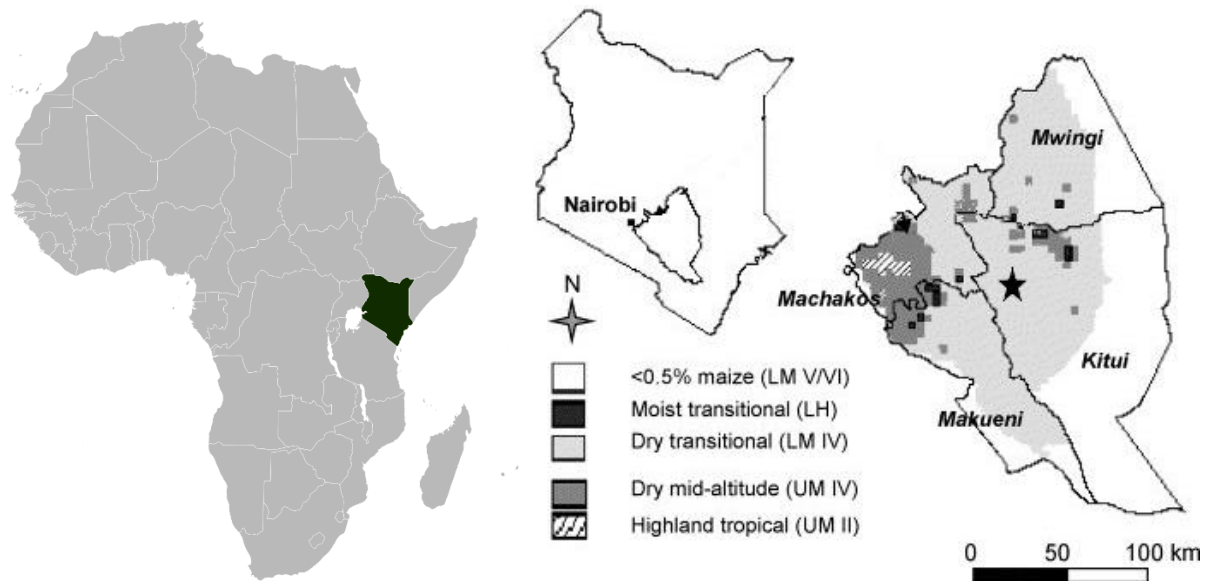

85 The ADOPT model has been applied to the context ~~of~~ of smallholder maize production in the dryland communities  
86 in the areas such as Kitui, Makueni ~~or~~ and Machakos in south-eastern Kenya (fig. 1). This semi-arid to sub-humid  
87 region is drought-prone, being hit by drought disasters in 1983/84, 1991/92, 1995/96, 1998/2000, 2004/2005, and  
88 2008-11, 2014-2018 (data from ~~Em-DAT~~ Em-Dat and DesInventar). ~~While T~~ the majority of the population in this  
89 dry transitional ~~and dry mid-altitude maize~~ farming zone is directly or indirectly employed through agriculture.  
90 However, technology adoption and production level remain rather low, making the region very vulnerable to  
91 droughts and climate change (Khisa & Oteng, 2014; Mutunga et al., 2017).

92 In Kenya, 75% of the country's<sup>2</sup> maize is produced by smallholder farms. Maize is grown in the two rainy  
93 seasons, with the aim to meet household food needs (subsistence farming) (Erenstein, Kassie, & Mwangi, 2011;  
94 Erenstein, Kassie, Langyintuo, et al., 2011; Speranza et al., 2008). While during the long rainy season (March-  
95 April-May) multiple crops are planted, the short rainy season (October-November-December) is considered the  
96 main growing season for maize in the region (Rao et al., 2011).

97 Reported smallholder maize yields often do not exceed 0.7 ton/ha. However, with optimal soil water management,  
98 maize yields can easily be around 1.3 ton/ha in the semi-arid medium potential maize growing zone in south-  
99 eastern Kenya (Omoyo et al., 2015). Few farmers use pesticides or improved seeds or other adaptation strategies  
100 (Tongruksawattana & Wainaina, 2019). In Kitui, Makueni and Machakos, the most preferred seed-variety is the  
101 high yielding but less drought resistant Kikamba/Kinyaya variety (120 growing days) with a potential yield of  
102 only 1.1 tons per hectare (Speranza, 2010; Recha et al., 2012). Trend analysis (1994-2008) shows that yields are  
103 declining due to the increasing pace of recurring droughts (Nyandiko, 2014).

104 Over 97% of the smallholder farmers in this area grow ~~#~~maize, mainly for own consumption or local markets  
105 (Brooks et al., 2009; Kariuki, 2016; Nyariki & Wiggins, 1997). It is the main staple food ~~for the people~~, providing  
106 more than a third of the caloric intake, and is also the primary ingredient used in animal feeds in Kenya (Adamtey  
107 et al., 2016; FAO, 2008).

108 ~~In the south-eastern Kenyan dry mid-altitude farming zone, smallholder farmers produce ten to twenty 90kg bags~~  
109 ~~of maize per year, grown in the two rainy seasons to ensure adequate supplies to meet household food needs~~  
110 ~~(Erenstein, Kassie, & Mwangi, 2011; Erenstein, Kassie, Langyintuo, et al., 2011; Speranza et al., 2008). While~~  
111 ~~during the long rainy season (March-April-May) multiple crops are planted, the short rainy season (October-~~  
112 ~~November-December) is considered the main growing season for maize in the region (Rao et al., 2011). Only~~  
113 about 20% of the farmers is-are able to sell their excess crops, while 66% has to buy maize to complement their  
114 own production (Muyanga, 2004). ~~Few farmers use pesticides or improved seeds or other adaptation strategies~~  
115 ~~(Tongruksawattana & Wainaina, 2019)~~

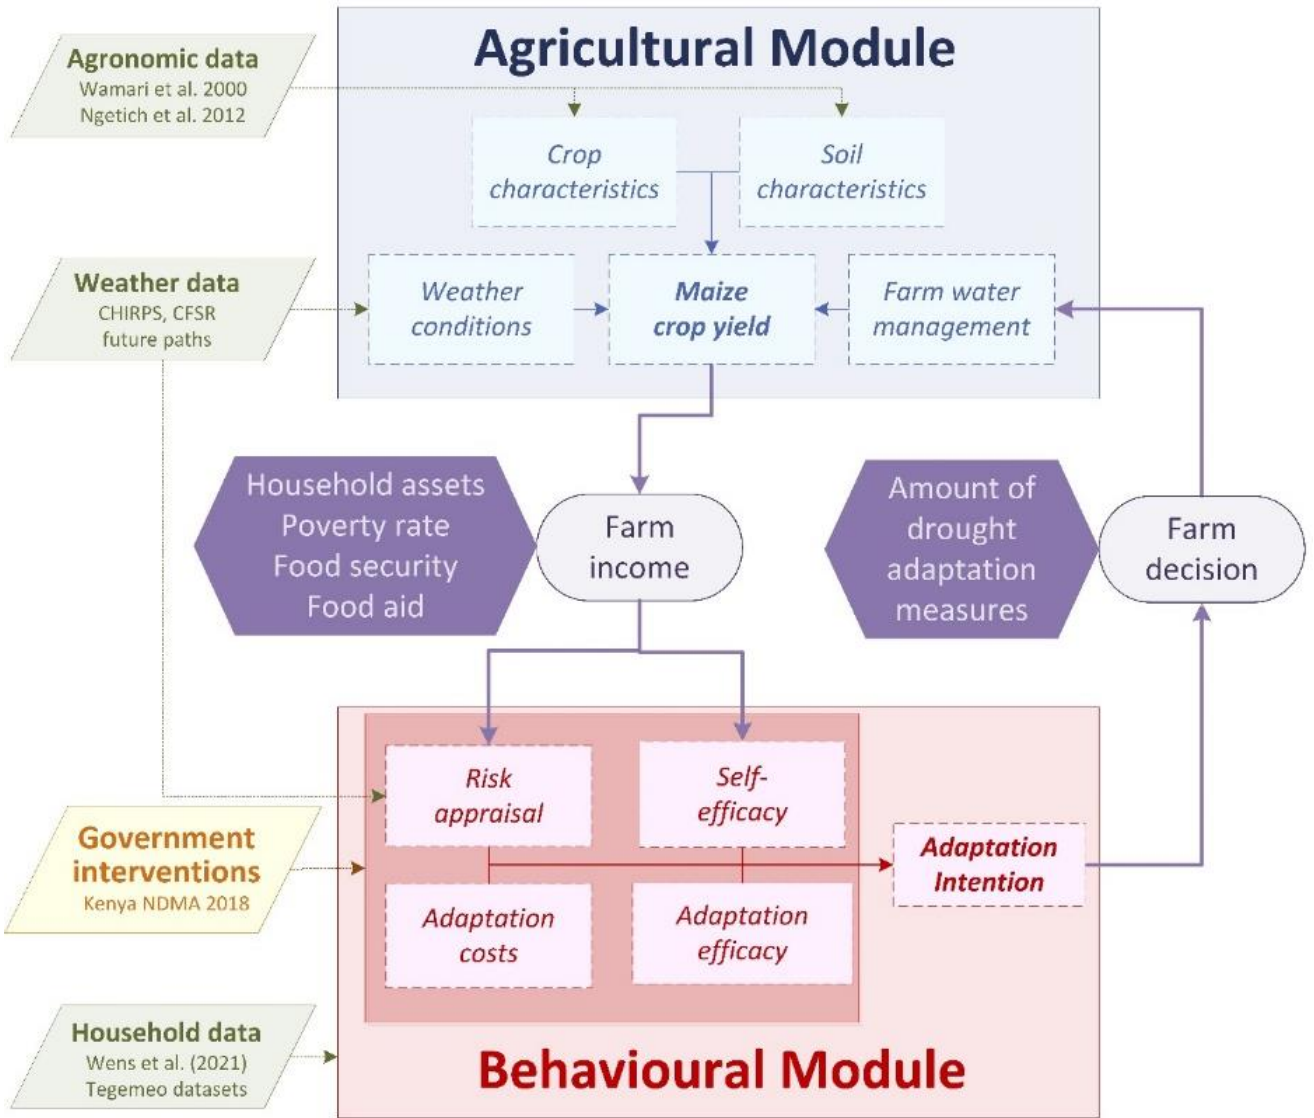

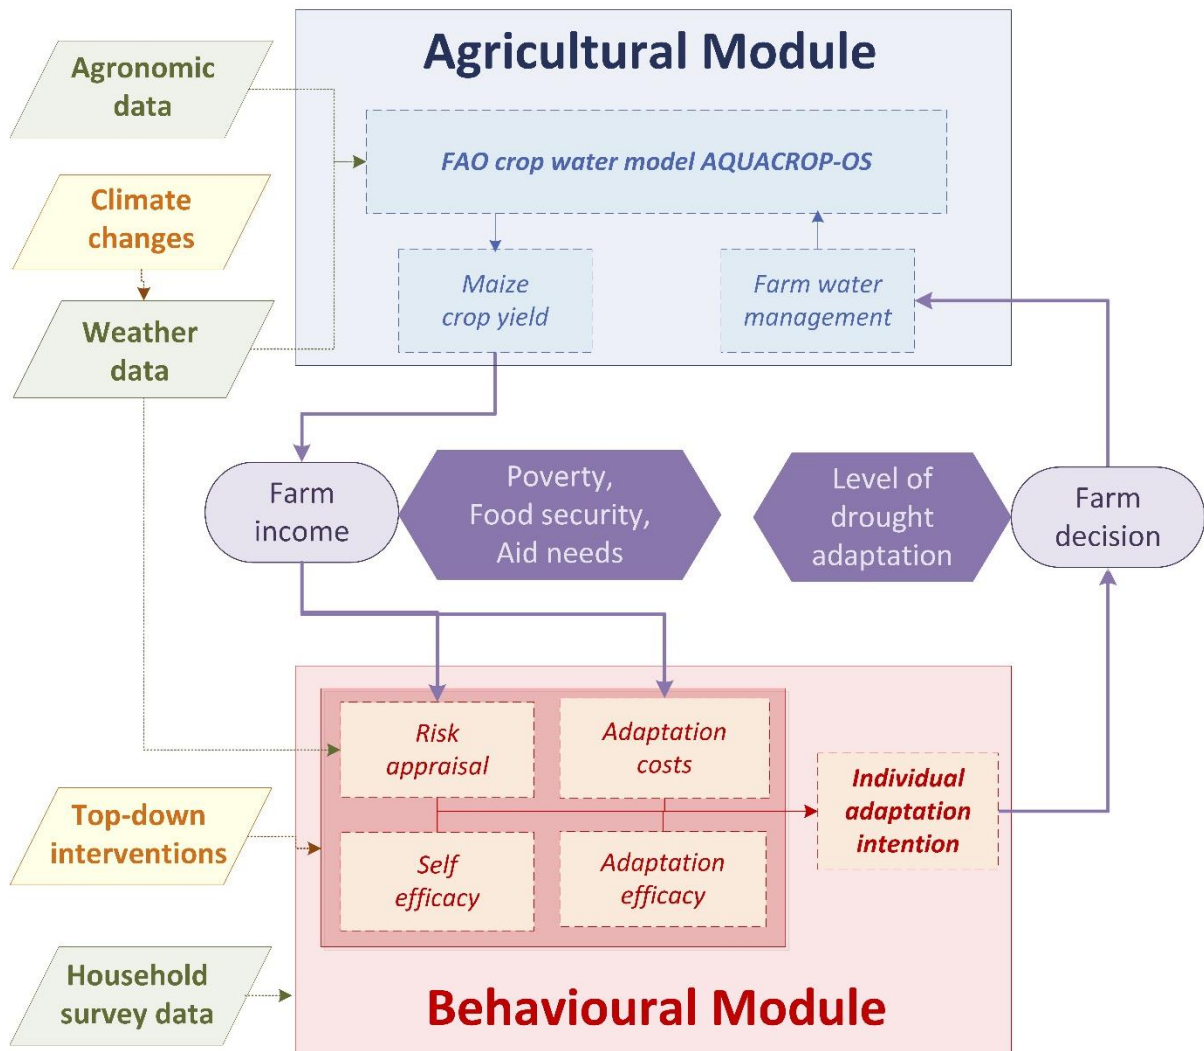

116 Figure 1: Study area: dry transitional South-Eastern Kenya maize agro-ecological zones (right) located in South-  
117 Eastern Kenya (centre) in the Horn of Africa (left). Area of where the survey data (Wens 2021) is collected is  
118 indicated with a star on the right map. Map adjusted from Barron and Okwach (Barron & Okwach, 2005)  
119

### 120 3 Model and scenario description

121 ADOPT (fig. 2, Wens et al 2020, adjusted-ODD+D (Overview, Design concept, Details, + Decision) protocol in  
122 Appendix A) is an agent-based model that links a crop production module to a behavioural module evaluating the  
123 two-way feedback between drought impacts and drought adaptation decisions. ~~For this study,~~ ADOPT was  
124 parameterized with information from expert interviews, a farm household survey with 2650 households including  
125 a semi-structured questionnaire and a discrete choice experiment executed in the Kitui Region, Kenya (Wens et  
126 al. 2021). Moreover, a discrete choice experiment (a quantitative method to elicit preferences from participants  
127 without directly asking them to state their preferred options) was executed to get information on changes in  
128 adaptation intentions under future top-down DRR interventions (Wens et al. 2021). This empirical data-set feeds

129 the decision rules in ADOPT ~~\_, which enables~~ describing farm households' adaptive behaviour in the face of  
130 changing environmental conditions (drought events), social ~~networks~~ ~~circumstances~~ ~~(actions of neighbouring~~  
131 ~~farmers~~ ~~farmer networks)~~, and ~~top-down~~ ~~(non-)governmental~~ interventions (drought management policies)  
132 ~~conditions~~. In ADOPT, crop production is modelled using AquacropOS (Foster & Brozović, 2018), simulating  
133 crop growth on a daily basis and producing crop yield values at harvest time twice per year. Calibrated for the  
134 Kenyan dryland conditions (Ngetich et al., 2012; Wamari et al., 2007), ~~ADOPT~~ ~~AquacropOS~~ ~~takes into~~  
135 ~~account~~ ~~considers~~ the current water management of the farm ~~(i.e., the applied drought adaptation measures)~~ and  
136 yields vary with weather conditions. The adaptive behaviour of the farm households (agents) is modelled based  
137 on the Protection Motivation theory (PMT, Rogers 1975). ~~This theory, which~~ was derived as ~~most suitable~~  
138 ~~promising~~ in an earlier study (Wens et al, 2020) and ~~has proved to best describe~~ ~~includes~~ ~~multiple relevant factors~~  
139 ~~that drive~~ the observed behaviour of farm households (Wens et al 2021). In this application of ADOPT, the model  
140 was run over 30 historical ~~al~~ years as baseline ~~then followed by~~ 30 years of ~~future~~ scenarios ~~(combinations of policy~~  
141 ~~interventions)~~ and climate changes; the start of these changes is indicated as "year 0") ~~scenarios~~. Through a  
142 ~~sensitivity analysis, both the average effect of individual adaptation decisions and its endogenous model~~  
143 ~~variability are analysed (similar to Wens et al 2020). We used, using~~ 12 different initialisations ~~per scenario to~~  
144 ~~include variations in model initialisation, the stochasticity that determines the individual adaptation decisions,~~  
145 ~~and the relative weights of factors influencing behaviour to allow for uncertainty in the relative importance of the~~  
146 ~~behavioural factors~~ (See 3.1).

148  
149 **Fig. 2: ADOPT model overview, adjusted from Wens et al., 2020. Description of the model (Overview, , Design concepts**  
150 **& Details) in Appendix A.**

151 **3.1 Individual adaptive behaviour in ADOPT**

152 Various soil water management practices, further called drought adaptation measures, can be adopted by  
153 smallholder farmers in ADOPT. There are shallow wells to provide irrigation water, the option to connect these  
154 to drip irrigation infrastructure, and Fanya Juu terraces as on-farm water harvesting techniques. Moreover, a soil  
155 protection measure reducing the evaporative stress, such as mulching, is included. These measures are beneficial  
156 in most – if not all – of the years and have a particularly good effect on maize yields in drought years. Nonetheless,  
157 but current adoption rates of these measures are quite varied and often remain rather low (Gicheru, 1990; Kiboi  
158 et al., 2017; Kulecho & Weatherhead, 2006; Mo et al., 2016; S. Ngigi, 2019; S. N. Ngigi et al., 2000; Rutten,  
159 2004; Zone, 2016).

160 Applying the PMT and using the empirical regression and correlation results of the households dataset, ADOPT  
161 applies the Protection Motivation Theory, a psychological theory often used to model farmer's bounded rational  
162 adaptation behaviour (Schriecks et al 2021). It describes how individuals adapt to shocks such as droughts and are

163 motivated to react in a self-protective way towards a perceived threat (Grothmann & Patt, 2005; Maddux &  
164 Rogers, 1983). ~~models-~~Four main factors determining farmers' adaptation intention under risk are modelled: (1)  
165 risk perception is modelled through the number of experienced droughts and number of adopted measures,  
166 household vulnerability, and experienced impact severity. Moreover, ~~th~~rust in early warnings is added, which can  
167 influence the risk appraisal if a warning is ~~sent~~ out. Coping appraisal is modelled through a (2) farmers' self-  
168 efficacy (household size / labour power, belief in ~~god~~God, vulnerability), (3) adaptation efficacy (perceived  
169 efficiency, cost and benefits, seasons in water scarcity, choices of neighbours, number of measures), and (4)  
170 adaptation costs (farm income, off-farm income, adaptation spending, access to credit). These four PMT factors  
171 receive a value between 0 and 1 and define a farmer's intention to adopt. Which smallholder farmers adopt which  
172 measures in which years is then stochastically determined based on this adaptation intention. More information  
173 regarding the decision making can be found in Appendix A.

### 174 3.2 Drought risk indicators in ADOPT

175 In ADOPT, ~~a~~Annual maize yield influences the income and thus assets of the ~~self-suffieient~~(largely) subsistence  
176 farm households. This influence is indirect, because the farm households are assumed to be both producers and  
177 consumers, securing their own food needs. ~~And-The influence is also~~it is a direct one, because ~~they-these farm~~  
178 households sell their excess maize on the market at a price sensitive to demand and availability. Farm households  
179 who cannot satisfy their food needs by their own production, ~~go~~turn to this same market. ~~They-and~~ buy the needed  
180 maize – if they can afford it and if there is still maize available on the market. If they ~~cannot-do not have the~~  
181 financial capacity or if there is a market shortage, they are deemed to be food insecure. ~~T,-and~~their food shortage  
182 (the kilogram maize short to meet household food demand) is multiplied by the market price ~~-to~~ estimate their  
183 food aid needs. Adding the farm income of the household with their income from potential other sources of  
184 income, it is estimated whether they fall below the poverty line of 1.9 USD per day. As climate and weather  
185 variability ~~let-causes~~ maize yields to fluctuate over time, so do the prevalence of poverty, the share of households  
186 in food insecurity and the total food aid needs. These factors can be seen as proxies for drought risk and were  
187 evaluated over time.

### 188 3.3 Climate change scenarios

189 Multiple climate change scenarios – all accounting for increased atmospheric carbon dioxide levels - were tested:  
190 a rising temperature of 10%, a drying trend of 15%, ~~and~~ a wetting trend of 15%, and various combinations of  
191 these. The warming and drying trends were based on a continuation of the trends ~~existing-observed~~ in the last 30  
192 years of daily NCEP temperature (Kalnay et al., 1996) and CHIRPS precipitation (Funk et al., 2015) data (authors'  
193 calculations; similar trends found in (Gebrechorkos et al., 2020)). The wetting trend was ~~based-inspired by~~on the  
194 projections from most climate change models which predict an increase ~~of-in~~ precipitation in the long rain season  
195 – a phenomenon known as the 'East African Climate Paradox' (Gebrechorkos et al., 2019; Lyon & Vigaud, 2017;  
196 Niang et al., 2015). The no change scenario was a repetition of the baseline period, without changing precipitation  
197 or temperature hence only elevated carbon dioxide levels. Reference evaporation was calculated for each scenario

198 using the Penman-Monteith model and thus influenced by temperature changes (Allen, 2005; Droogers & Allen,  
 199 2002).

200

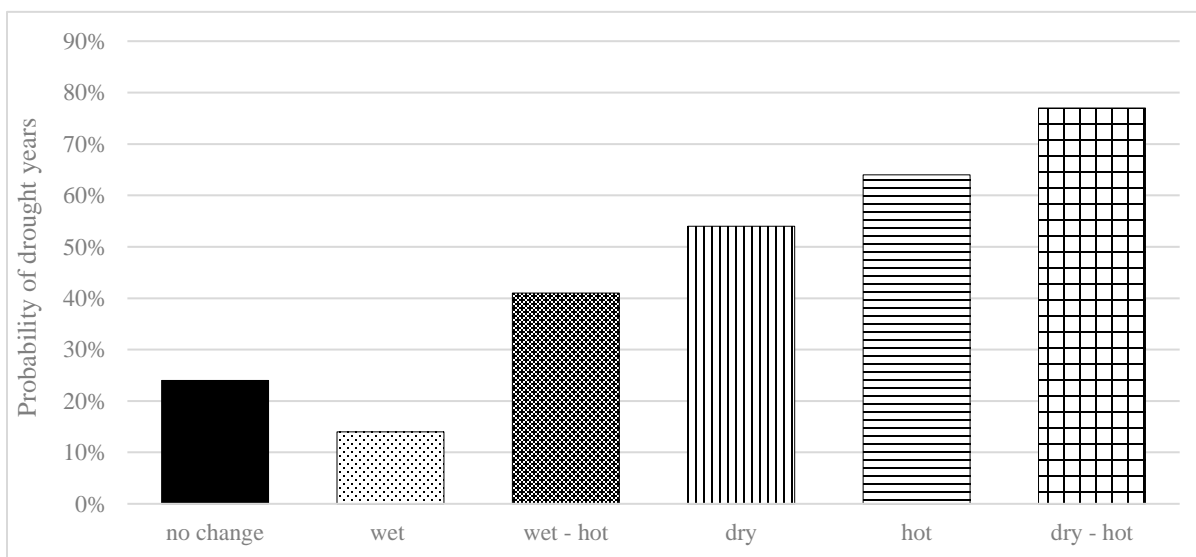

201 **Table 1: Average (daily temperature, annual precipitation) weather conditions (1980-2010) in ADOPT**

	min temperature	max temperature	precipitation	reference evaporation
<b>No change</b>	16.3 (+- 0.8) *C	26.9 (+- 0.9) *C	888 (+-319) mm	1547 (+-298) mm
<b>Wet</b>	16.3 (+- 0.8) *C	26.9 (+- 0.9) *C	1021 (+-367) mm	1547 (+-298) mm
<b>Hot</b>	17.9 (+- 0.9) *C	29.6 (+- 0.9) *C	888 (+-319) mm	1659 (+-320) mm
<b>Dry</b>	16.3 (+- 0.8) *C	26.9 (+- 0.9) *C	755 (+-271) mm	1547 (+-298) mm

202

203 These trends were added to time series of 30 years of observed data, ~~so as to simulate credible events and have a~~  
 204 ~~realistic day to day, month to month and even decadal variability.~~ While such approach does not account for an  
 205 ~~increased variability, it allows to account for the temporal coherence in the data and the interrelationships among~~  
 206 ~~different weather variables (weather generators – another option to downscale projected climate - have still some~~  
 207 ~~progress to make in order to accurately account for extreme events (Ailliot et al., 2015; Mehan et al., 2017)).~~ This  
 208 resulted of 30 years of synthetic ‘future’ data, for each of the six - wet, hot-wet, hot, dry, hot-dry and no change  
 209 - scenarios . While ~~such scenarios might they~~ not have a known probability of ~~occurring , as a possible change in~~  
 210 ~~frequency and extremeness of events is ignored, they occurring, they enable~~ allowed testing the robustness of the  
 211 ~~on-farm adaptationser~~ and government top-down drought ~~adaptation-disaster risk reduction~~ strategies under  
 212 changing average hydro-meteorological conditions. ~~This application of ADOPT ran over thirty years of baseline~~  
 213 ~~and then thirty years of climate change scenarios; its change indicated as “Year 0”.~~

214

215

216 **Fig. 3: Probability of having a year with three or more consecutive months under a SPEI < -1, for the climate change**  
 217 **scenarios.**

218 Droughts, here defined as at least three months with standardized precipitation index (SPEI) values below – 1 ,  
 219 have a different rate of occurrence under these different future climate scenarios (Fig. 3). SPEI is calculated  
 220 through standardizing a fitted GEV distribution over the historical monthly time ~~series, and series and~~  
 221 superimposing this onto the climate scenario time series. Under the no change scenario, 25% 59 ~~of the months~~

222 ~~thirty simulated years between 2015-2045~~ fall below this threshold. ~~Under the wet scenario, less such fewer~~  
223 ~~droughts occur (15% of the years), but, this is lowered to 34 months under the wet scenario. U~~ ~~under the hot-dry~~  
224 ~~conditionssscenario~~, the number of ~~droughtdroughts months-years~~ more than doubles ~~to 123 months(54% of the~~  
225 ~~years)~~. Temperature is dominant over precipitation is determining drought conditions, as under the hot-wet  
226 scenario, ~~97-41%~~ drought ~~months-years~~ are recorded, and ~~even 157~~ under hot-dry conditions, ~~78% of the years~~  
227 ~~can be considered drought years~~.

### 228 3.4 Drought risk reduction intervention scenarios

229 ~~Farmers' adaptive behaviour can be influenced by external policies and (non-)governmental drought risk~~  
230 ~~reduction interventions.~~ Kenya Vision 2030 for the ASAL promotes drought management through extension  
231 ~~services, andservices and~~ aims to increase access to financial services such as affordable credit schemes  
232 (Government of Kenya, 2012; Kenya, 2016). ~~FurthermoreBesides~~, building on the Ending Drought Emergencies  
233 plan, the National Drought Management Authority prioritizes the customization, improvement and dissemination  
234 of drought early warning systems. ~~It, and~~ aims to establish trigger levels for ex-ante cash transfer so as to upscale  
235 drought risk financing (Government of the Republic of Kenya, 2013; National Drought Management Authority,  
236 2015; Republic of Kenya, 2017). Improved extension services tailored to the changing needs of farm households  
237 (Muyanga & Jayne, 2006), ~~a~~ better early warning system with longer lead times (Deltares, 2012; van Eeuwijk,  
238 n.d.), ex-ante cash transfers to the most vulnerable when a drought is expected (Guimarães Nobre et al., 2019)  
239 and access to credit-markets (Berger et al., 2017~~5~~; Fan et al., 2013), are all assumed to increase ~~farmers'~~ intention  
240 to adopt new measures.

241 As shown in Wens et al (2021), extension services are best offered to younger, less rich and less educated people,  
242 or to ~~those~~ who already adopted the most common measures, ~~to have a big influence on the adoption intentions~~.  
243 Similarly, early warning systems are appreciated more by less educated, less rich farmers, or those not part of  
244 farmer knowledge exchange groups. The ex-ante cash transfer instigates those who spend already a lot of money  
245 on adaptation, to adopt more expensive measures the most. Access to credit is preferred by less rich farmers, ~~how~~  
246 ~~who~~ have a larger land size, are members of a farm group, went to extension trainings, have easy access to  
247 information and/or are highly educated (Wens et al. 2021).

248 In this application of ADOPT, the effect of these four interventions - extension services, early warning systems,  
249 ex-ante cash transfer and credit schemes - were tested individually. Additionally, three scenarios, combining  
250 different types of interventions, were evaluated, all initiated in year "0" in the model run.~~;~~

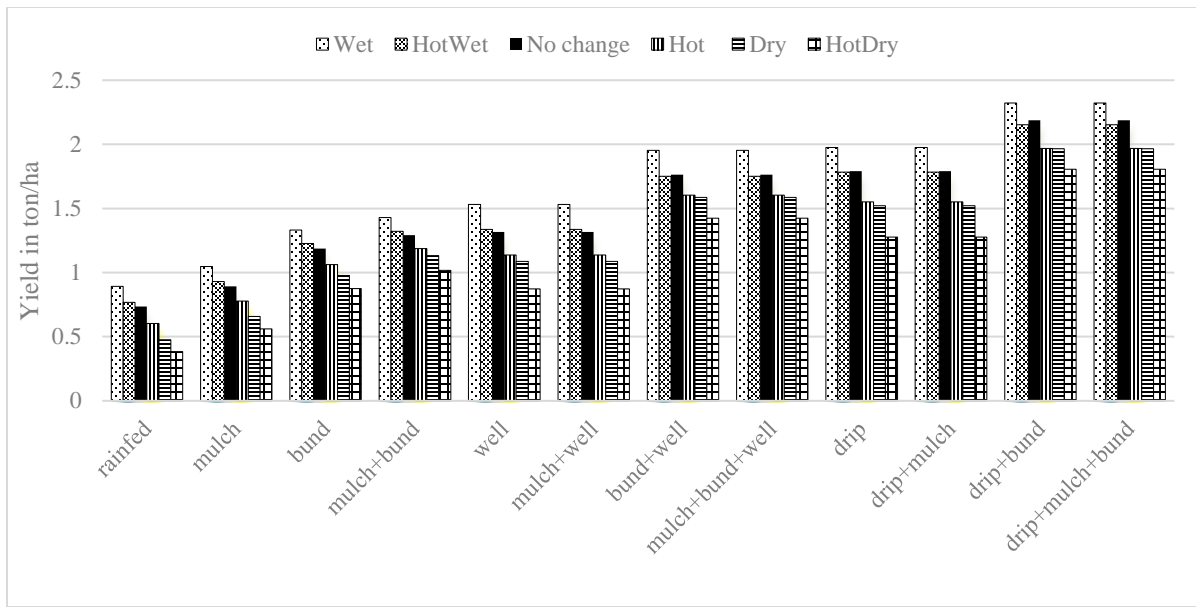

252

- 253 1. Reactive ~~(non-)governmental~~policy intervention “supporting drought recovery”: Emergency aid is given to  
254 farmers who lost their livelihoods after drought disasters; this food aid is distributed to farmers who are on  
255 the verge of poverty to avoid famine.
- 256 2. Pro-active ~~(non-)governmental~~policy intervention plan “preparing for drought disasters”: Early warnings are  
257 sent out each season if a drought is expected. This is assumed to raise all farmers’ risk appraisal with 20%.  
258 Ex-ante cash transfers are given to all smallholder farmers (those without income off-farm and without  
259 commercialisation) to strengthen resilience in the face of a drought. This is done when severe and extreme  
260 droughts (SPEI <-1, and <-1.5) are expected that could lead to crop yield lower than respectively 500kg/ha  
261 and 300kg/ha. Money equivalent to the food insecurity following these yields is paid out to farmers with low  
262 external income sources. ~~Lastly~~Moreover, like in the reactive government scenario, emergency aid is given to  
263 farmers who need it.
- 264 3. ~~Strategie~~Prospective ~~(non-)governmental~~policy intervention plan (UNDRR 2021) “mitigating (future)  
265 drought disasters”: Credit rates are lowered so that it is affordable to people to take a loan for adaptation  
266 measures, at an interest rate of 2% and a pay-back period of five years. Besides, frequent trainings are given  
267 in communities with poor practices to improve their ~~human~~capacity related to drought adaptation practices  
268 for agriculture. Moreover, like in the pro-active government scenario, an improved early warnings system is  
269 set up and ex-ante cash transfer is given. Lastly, emergency aid is given to farmers who need it.

## 270 4. Results

### 271 4.1 Maize yield under different adaptation measures and future climate scenarios

272 The annual average maize yields under the different climate scenarios, for ~~all of~~ the four on-farm water  
273 management/drought adaptation measures ~~that can be adopted by the smallholder farmers~~implemented in ADOPT  
274 - mulch, ~~fanya~~Fanya juuJuu bunds, shallow wells and drip irrigation -, were calculated using AquacropOS (Fig.  
275 4). Under wetter future climate conditions, maize yields are expected to increase under all management scenarios,  
276 with mulch having a particular positive effect on the soil moisture conditions throughout the full growing season.  
277 Hotter climate conditions reduce yields slightly ~~;- and~~ the assumptions in this model on the frequency and amount  
278 of manual irrigation or drip irrigation water are not sufficient to diminish this effect, even under wetter conditions.  
279 Paired with drier conditions, this hotter future has dramatically negative effects on yields, showing on average  
280 28% lower yields compared to the no climate change scenario over all management scenarios.

281

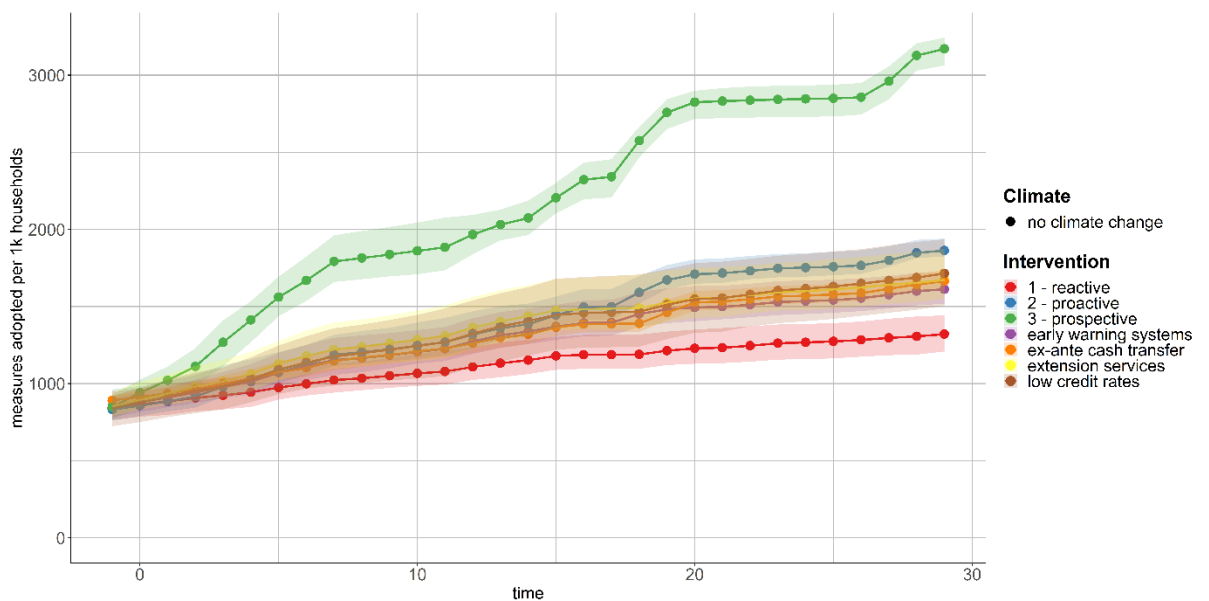

282 **Fig. 4: Average maize yield under different agricultural water management drought adaptation measures conditions**  
 283 **and different future climate scenarios.**

284 **4.2 The adoption of adaptation measures over time**

285 In ADOPT, all evaluated (non-)governmental top-down (?) interventions increased the adoption rate of the  
 286 evaluated adaptation measures compared to the reactive “no intervention” scenario (Fig.5): This means that  
 287 adaptation intention is indeed limited by a low risk perception, high (initial) adaptation costs, a limited knowledge  
 288 of the adaptation efficacy or a low self efficacy. These barriers are alleviated through the different government  
 289 interventions reduced credit rates, improved early warning systems, tailored extension services, and ex-ante cash  
 290 transfers, as well as the proactive and prospective scenarios, leading to various increases in adoption as compared  
 291 to the reactive scenario (colours in Fig. 5).

292

293

294 **Fig. 5: Total amount of measures adopted per 1000 initialized households under no climate change, averaged over all**  
 295 **runs. The shaded area indicates the variation - uncertainty introduced by different model initialisations and by**  
 296 **different relative importance of the PMT factors on the decisions of households (sensitivity analysis). Year 0 initiates**  
 297 **climate change scenarios (indicated with different marker shapes), and (non-)governmental policy drought risk**  
 298 **reduction interventions (indicated with different line colours).**

299

300 Looking into detail to the effect of possible (non-)governmental policy interventions (Fig. 5, table B2 in Appendix  
 301 B), affordable credit schemes had the is-highest effect on the adoption rate of drought adaptations measures.  
 302 Furthermore, ex-ante cash transfers (which cannot be seen as large sums of investment money but as a mere  
 303 means to keep families food secure) were more effective to increase adoption of the more affordable measures.

304 Indeed,— richer families mostly had already adopted these measures before ~~(non-)governmental policy~~  
305 interventions were in place. Extended extension service training increased the adoption of less popular measures  
306 and decreased the adoption of the popular but not as cost-effective ~~fanya~~Fanya juu terraces. Early Warning  
307 Systems ~~surprisingly~~ had more effect in the ~~more wet~~wetter climate conditions. ~~T,~~ as the dry-hot scenario ~~had~~ has  
308 so many drought episodes that risk perception is automatically high while the alert lowers when droughts become  
309 ~~more scarce~~scarcer in the less dry scenarios.

310 Overall, although the processes through which the interventions support households to adapt differ significantly,  
311 the differences in eventual adoption rate under the different interventions were small (they overlap in uncertainty  
312 interval). Also, the effect of climate change on the adoption rate (Figure B1 in Appendix B, table B2 in Appendix  
313 )— was rather small when evaluating the reactive (no intervention) scenario. However, with interventions, the  
314 climate change scenarios differed more.

315 When examining the effect of the three intervention scenarios (Figure B2 in Appendix B; table B2 in Appendix  
316 B), it is clear that implementing multiple ~~interventions~~ policies at once ~~—~~ resulted ~~—~~ in an stronger increase in  
317 adoption: ~~— which can be explained by the alleviation of various adoption barriers at once. Averaging over all~~  
318 ~~adaptation measures,~~ a proactive and ~~strategie~~prospective intervention plan ~~would~~ increased ~~adaptation~~ the  
319 adoption of different adaptation measures with respectively 40% and 140% more than under the “~~no~~  
320 ~~intervention~~reactive, no climate change” scenario where no intervention takes place. Both a proactive and  
321 ~~strategie~~prospective ~~(non-)government~~ approach increased the adoption of cheaper adaptation measures to close  
322 to 100% of the farm households. For the more expensive measures, the proactive scenario showed to be less  
323 effective while the ~~strategie~~prospective scenario reached quite high adoption rates in the more extreme climate  
324 scenarios.

326  
 327 **Fig. 6: Household maize harvest (kg/year, sum of two growing seasons) over 30 ‘scenario years’ under different climate**  
 328 **change and (non-)governmental policy intervention scenarios. The shaded area indicates the variation - uncertainty**  
 329 **introduced by different model initialisations and by different relative importance of the PMT factors on the decisions**  
 330 **of households (sensitivity analysis). The shaded area shows the uncertainty range introduced by adding a sensitivity**  
 331 **test on the parameterisation of variables describing the adaptive behaviour of the households (i.e. the relative weights**  
 332 **of the different determinants of the protection motivation theory).**

333 The adoption of adaptation measures by households influenced their maize yield and thus affected the average  
 334 and median maize harvest under the different future climates and drought risk reduction interventions (Fig. 6).  
 335 This is-becomes clear comparing the first thirty baseline years with the following thirty scenario years: -When no  
 336 (non-)governmental policy interventions were in place, average maize yields increased with almost 30% under a  
 337 wet-hot future and decreased over 25% under a dry-hot climate. Under a strategieprospective government  
 338 supporting the adoption of adaptation measures, average maize yields increased up to 100% under a wet-hot future

339 and increased with over 60% under dry-hot future conditions. Clearly, an increased uptake of measures under this  
340 intervention scenario did offset a potentially harmful drying climate trend.

### 341 4.3 Drought risk dynamics under policy and climate change

342 Assuming off-farm income to fluctuate randomly but not steadily increasing or decreasing, the changing harvests  
343 over time directly affected the poverty rate and the share of households in food insecurity (Fig. 7). Both trends in  
344 yield caused by droughts ~~—and thus climate change—~~ or by the adoption of new adaptation measures ~~—potentially~~  
345 ~~instigated by (non-)governmental interventions—~~, could drive farm household ~~depended on agricultural income~~  
346 in or out of poverty. Running ADOPT with a reactive and no climate change scenario, a slight increase of 5  
347 percentage points (pp)% in poverty levels was visible. Poverty levels increased up to 15~~pp%~~ compared to the  
348 baseline situation, when a dryer and/or hotter climate scenario was run. A proactive intervention plan reduced  
349 poverty ~~with by~~ 11~~pp%~~ under no climate change. ~~I, and in~~ the dry-hot climate scenario this combination of  
350 improved early warning systems and ex-ante cash transfers lead to reductions of 20-30~~pp%~~ compared to the  
351 baseline years. However, the ~~strategie~~prospective government scenario showed the most prominent results,  
352 projecting reductions of 45~~pp%~~ under no climate change and around 60~~pp%~~ under dryer and hotter climate  
353 conditions.

354

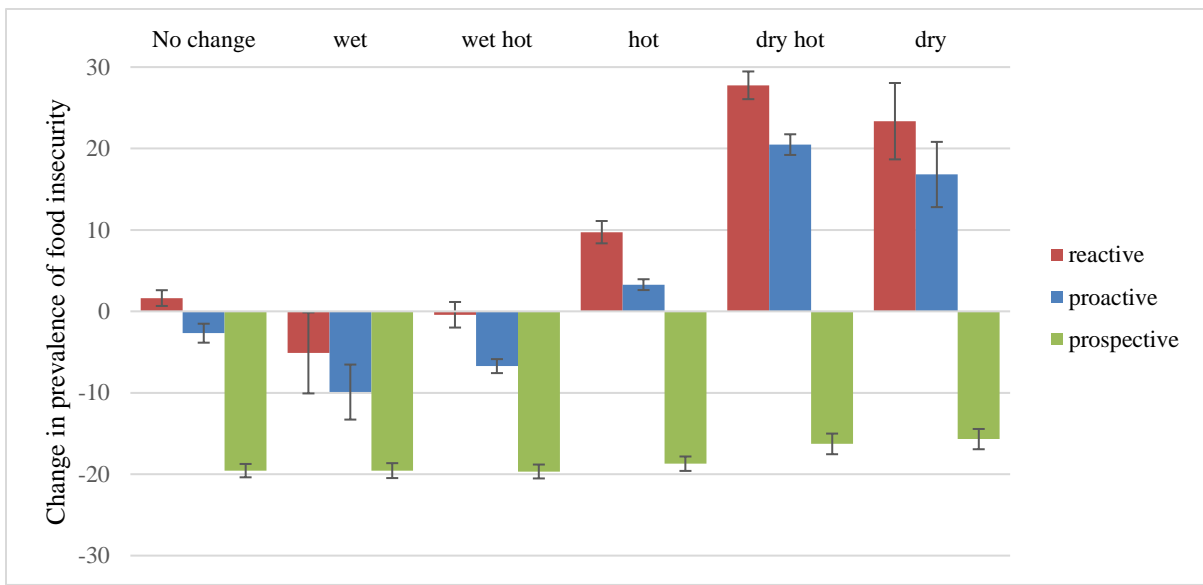

355

356 **Fig. 7: Share of households in poverty (earning under the 2USD/day income line, under different climate and (non-)**  
 357 **governmental policy intervention scenarios). The shaded area indicates the variation - uncertainty introduced by**  
 358 **different model initialisations and by different relative importance of the PMT factors on the decisions of households**  
 359 **(sensitivity analysis). The shaded area shows the uncertainty range introduced by adding a sensitivity test on the**  
 360 **parameterisation of variables describing the adaptive behaviour of the households (i.e. the relative weights of the**  
 361 **different determinants of the protection).**

362 Food insecurity is partly caused by a lack of income or assets, but also by the farm market mechanism. Droughts,  
 363 climate change and adaptation levels influence the availability of maize on this market. Farm households which  
 364 do not produce enough to be self-sufficient, buy maize on the market if they have the money and if there is maize  
 365 locally available. Households are assumed to be in food shortage if they have to rely on food aid to fulfil their  
 366 caloric needs. While on average in the 'no climate change' and 'no (non-)governmental policy interventions'

367 scenarios, food security rates were predicted to remain stable compared to the baseline period (fig. 8). However,  
 368 (non-)governmental policy interventions and climate change can alter this balance.  
 369 Improving extension services or providing ex-ante cash transfers individually showed on average 7.5% more  
 370 reduction in food insecurity than the reactive government scenario. Improved early warning systems showed on  
 371 average - over all climate scenarios- an increased reduction of 4.5%. It should be kept in mind that ADOPT does  
 372 not take into account consider (illicit) coping activities in the face of droughts such as food stocking or charcoal  
 373 burning. However, —both of them might reduce the food security threat. Credit schemes at 2%, individually, lead  
 374 to more than 8% reduction in food insecurity levels as compared to the reactive scenario; but even then, on  
 375 average net food insecurity rates increase due to climate change. A proactive intervention resulted in a food  
 376 insecurity rate which is 6 percent points lower than under the reactive scenario; but still showed increases in the  
 377 prevalence of food insecurity under hotter and drier conditions. A strategieprospective intervention, combining  
 378 all four interventions, was able to consistently reduce the food insecurity levels over time, even under the dry-hot  
 379 climate scenario. This scenario was able to counteract the increase in food insecurity, achieving a reduction of  
 380 households in food insecurity-shortage over time with on average 74.28% compared to the reactive scenario, all  
 381 climate scenarios considered.

382

383

384 **Fig. 8: Percent-Absolute change (average and standard deviation introduced by sensitivity analysis - variation caused**  
 385 **by different model initialisations and by different relative importance of the PMT factors on the decisions of**  
 386 **households) in average share of households in food shortage of the 230 last years of scenario run, compared to the first**

387 230 years of baseline run before “year 0“, under different climate and ~~(non-)governmental policy~~ intervention  
 388 scenarios. ADOPT model output.

389 Expressing drought impacts in average annual food aid required (in USD) (in USD, assuming a maize price for  
 390 shortage markets, as price volatility is taken into account—see ODD+D in Appendix A) can help to evaluate the  
 391 effect of different climate change scenarios or different ~~(non-)governmental policy~~ intervention scenarios on the  
 392 drought risk of the community. These estimations are translated to USD, assuming a maize price for shortage  
 393 markets, as price volatility is considered. Table 2 shows the change in aid needs compared to the no-climate  
 394 change, no-~~governmental-top-down~~ intervention baseline period (based on the 1980-2000 situation). When  
 395 assuming no climate change, it seemed that the community is stable, only slightly increasing the share in  
 396 vulnerable households. More measures were adopted as information is disseminated through the farmer networks,  
 397 but those who stay behind will face lower sell prices as markets get more stable and have a harder time  
 398 ~~accumulating assets~~accumulating assets. Under wetter conditions, reductions in drought emergency aid did  
 399 reduce. However, drier, hotter climates had a detrimental effect on the food needs, with more vulnerable people  
 400 crossing the food shortage threshold.

401 Under the no climate change scenario, each of the four ~~(non-)governmental policy~~ interventions did cause a  
 402 reduction in aid needs, with credit schemes having the largest effect. Under wetter conditions, they also increased  
 403 the reduction of aid needs compared to the reactive scenario. However, no individual measure, was able to offset  
 404 the effect of hotter and drier climate conditions. Even under a proactive intervention, there would still be an  
 405 increase in aid needs under such climate conditions. Only under the strategieprospective intervention scenario, a  
 406 decrease in aid needs was visible under all possible climate change scenarios.

407 **Table 2: Change in aid needs (%) in 2030-2050 compared to 1980-2000 (average and standard deviation introduced by**  
 408 **sensitivity analysis - variation caused by different model initialisations and by different relative importance of the PMT**  
 409 **factors on the decisions of households) under different climate and ~~(non-)governmental policy~~ intervention scenarios.**  
 410 **ADOPT model output.**

411

412 5. Discussion

413 5.1 The effect of early warning, extension services, ex-ante transfers and low interest rates

414 Under a reactive strategy (“no intervention”) and assuming no climate change, a slow but steady adoption of  
415 mulch, ~~fanya~~Fanya juuJuu, shallow well and irrigation practices is estimated. This is a result of an ever increasing  
416 information diffusion through the farmer networks and existing extension services, as also found in (Hartwich et  
417 al., 2008a; van Duinen et al., 2016a; Villanueva et al., 2016; Wossen et al., 2013). Yet, multiple smallholder  
418 households still suffer from the effects of droughts, indicated by the elevated food insecurity rates and poverty  
419 rates. While ~~many~~some can break the cycle of drought and subsequent income losses, others are trapped by  
420 financial or other barriers and end up in poverty and recurring food insecurity. This is, as also found in by e.g. e.g.,  
421 Enfors & Gordon, (2008); Mango et al., (2009); Mosberg & Eriksen, (2015); Sherwood, (2013). In the reactive  
422 scenario, it is clear that adaptation intention is limited by factors such as a low risk perception, high (initial)  
423 adaptation costs, a limited knowledge of the adaptation efficacy or a low self-efficacy. Some of these barriers are  
424 alleviated through the different government interventions.

425 As compared to this reactive scenario~~Under all policy interventions, an~~ increased rate of adoption is observed  
426 for all policy interventions. This translates into a comparatively lower drought risk -(expressed by the indicators:  
427 community poverty rate, food security and aid needs)as compared to the “no intervention” assumption~~trend~~  
428 ~~confirms the results by. -but the positive effect on household resilience varies. designed~~influence , and of  
429 measures by communities to expressed by the indicators: While initially extension services have the largest effect  
430 on the adoption of on-farm drought adaptation measures, over time access to credit results in the highest adoption  
431 rates and is also estimated to decrease emergency aid the most. ~~While~~Tthe former, alleviating the knowledge  
432 (self-efficacy) barrier, increases adoption under no climate change with 27% as compared to no intervention. It is  
433 indeed widely recognized as an innovation diffusion tool in different contexts (e.g. e.g., Aker, 2011; Hartwich et  
434 al., 2008b; Wossen et al., 2013). ~~T~~the latter, alleviation the financial (adaptation costs) barrier, increases adoption  
435 under no climate change with 30% as compared to no intervention. It is is also only found to be an effective policy  
436 to reduce poverty in Ghana by Wossen and Berger (Wossen & Berger, 2015). Ex-ante cash transfers also tackle  
437 the financial barrier but less effectively (the cash sum is small and fixed – only significant for less wealthy  
438 households), increasing adoption under no climate change with 25% as compared to no intervention. This matches  
439 ~~e~~Empirical evidence for on thethe positive effects of ex-ante cash transfers ~~exists~~-(Asfaw et al., 2017; Davis et  
440 al., 2016; Pople et al., 2021). ~~However, ADOPT, and the~~ model estimations might be an underestimation as  
441 ~~ADOPT~~the model does not account for many preparedness strategies of households such as stocking up food  
442 while the price is still low, fallowing land to reduce farm expenses, or searching for other sources of income  
443 (Khisa & Oteng, 2014). Seasonal early warning systems, and which -raise awareness of upcoming droughts,  
444 increase the adoption of measures with -22% as compared to no intervention. Early warnings have a stronger  
445 effect on the adoption of mulching or Fanya Juu (cheaper measures, lower financial barrier) than on drip irrigation.  
446 Clearly, -but the positive effect of the interventions on household resilience varies, which is confirmed by the  
447 empirical findings of Wens et al. 2021.

448 ~~Comparing these results to the discrete choice model results of Wens et al. 2021 (Wens et al 2021, table 7) in~~  
449 ~~more detail, we see an underrepresentation of the effects of early warning systems (people estimate that receiving~~  
450 ~~a seasonal warning for drought will highly steer them to adapt). Affordable and accessible credit does show a~~  
451 ~~significant effect in Wens et al 2021, especially when considering is the effect per percentage reduction in interest~~  
452 ~~rate. Also similar to the model runs, ex ante cash has a less significant and smaller effect—especially when~~  
453 ~~controlling for covariance (Wens et al 2021, table C).~~

454 The proactive government scenario, “preparing for drought disasters” by improving early warning systems and  
455 supporting ex-ante cash transfers, ~~is estimated to level poverty and food security under most climate change~~  
456 ~~scenarios but not under dry conditions~~ has a larger effect on drought risk. However, this effect is not as much as  
457 the sum of the effect of the two interventions. ~~Empirical evidence for the positive effects of ex ante cash transfers~~  
458 ~~exists (Asfaw et al., 2017; Davis et al., 2016; Pople et al., 2021), and the model estimations might be an~~  
459 ~~underestimation as ADOPT does not account for many preparedness strategies of households such as stocking up~~  
460 ~~food while the price is still low, fallowing land to reduce farm expenses, or searching for other sources of income~~  
461 ~~(Khisa & Oteng, 2014).~~

462 In contrast, ~~t~~he prospective government scenario “mitigating drought disasters” by combining all four  
463 interventions, alleviates multiple barriers to adoption at once. ~~This,~~ creates ~~ing~~ a significant, non-linear increase  
464 in adoption, ~~matching the significant positive correlation between the preferences for extension, credit, early~~  
465 ~~warning in Wens et al. 2021.~~ Consequently, this scenario results in a clear growth in resilience of the farm  
466 households, shown in more stable income, lower poverty rates and less food insecurity.

## 467 **5.2 The robustness of drought risk reduction interventions under climate change**

468 Climate change influences the effectivity of the measures as well as farm households’ experience with droughts.  
469 Under all climate change scenarios, a lower adoption of adaptation measures compared to the “no climate change”  
470 assumption is observed. ~~It shows~~ This could be explained by the fact that the perceived need to adapt, ~~or risk~~  
471 ~~appraisal,~~ is lower under wet conditions and the financial strength to adapt, ~~or coping appraisal,~~ is lower under  
472 dry or hot conditions. This highlights—showing two different barriers to adoption: risk appraisal lowers when the  
473 occurrence of drought impacts is less frequent, while coping appraisal lowers due to experiencing more drought  
474 impacts. This link between drought experiences, ~~or~~ poverty and adaptation was also found in other studies  
475 (e.g.e.g., Gebrehiwot & van der Veen, 2015; Holden, 2015; Makoti & Waswa, 2015; Mude et al., 2007; Oluoko-  
476 Odingo, 2011; Winsen et al., 2016)

477 While their effect on the adoption rates seems rather small, ~~t~~he ~~different~~ diverse climate change scenarios ~~portray~~  
478 have a distinctly different effect on the ~~development~~ evolution of drought risk in ~~of~~ the rural communities. Due to  
479 the adaptation choices of the farm households, average maize harvests are estimated to slightly increase under the  
480 “no climate change” scenario. A, ~~and a~~ major increase is estimated under wet and wet-hot conditions where both  
481 increased adoption and ~~reduced droughts~~ better maize producing weather conditions play a role. Under hot, dry  
482 and dry hot conditions, the average household harvests are estimated to decrease (also found in Wamari et al.,  
483 2007). ~~Increases~~ in median and mean assets (household wealth) are estimated slightly increase under the no

484 climate change scenario. In this case, adaptation efforts are able to reducing the drought disaster risk. Drier  
485 climates might lead to decreases in median and mean assets, if farm households are not supported through top-  
486 down interventions. ~~Hand~~ hotter climates are estimated to result decreased median but increased average assets  
487 of the households. In this case, adaptation rates are not high enough to avoid increasing drought risk for the  
488 -median households. ~~Clearly, the potential future climates very much influence the potential future socio-economic~~  
489 development of smallholder farm households.

490 The proactive government scenario, “preparing for drought disasters” is estimated to level poverty and food  
491 security under most-hotter or drier climate change scenarios ~~but not under dry conditions~~. The prospective  
492 government scenario is the only scenario estimated to reduce emergency aid under all possible future climates.  
493 However, it should be noted that it takes one to two decades to make a significant difference between the reactive  
494 stance and prospective intervention plan. In other words: with climate change effects already visible through an  
495 increased frequency of drought disasters, and more to be expected within the following 10-20 years, ~~—~~ prospective  
496 interventions should be taken-started now in order to be benefit from the increased resilience in time under any  
497 of the evaluated futures.

### 498 5.3 ADOPT as a dynamic drought risk adaptation model

499 While ABMs have the potential to represent full ‘closed loop’ couplings of environmental and social subsystems,  
500 this has long not been the standard practice (Filatova et al., 2013). ~~However, in-~~ In the past decade, the use of  
501 ABMs in ex-post and ex-ante evaluations of agricultural policies and agricultural climate mitigation has been  
502 progressively increasing (Huber et al., 2018; Kremmydas et al., 2018). A pioneer in agricultural ABM is Berger  
503 (2001) who couples economic and hydrologic components into a spatial multi-agent system-. This is followed  
504 more recently by for example Berger and Troost (2011), Van Oel and Van Der Veen (2011), Mehryar et al.  
505 (2019) and Zagaria et al. (2021). The socio-hydrological, agent-based ADOPT model follows this trend in that it  
506 fully couples a biophysical model—AquacropOS—and a social decision model—simulating adaptation decisions  
507 using behavioural theories—through both impact and adaptation interactions.

508 ~~Moreover, t~~ The initial ADOPT model setup was created through interviews with stakeholders (Wens et al. 2020),  
509 and the adaptive behaviour is based on both existing economic – psychological theory and on empirical household  
510 data (Wens et al. 2021). The assumption of heterogeneous, bounded rational behaviour is ~~precedented~~ addressed  
511 yet only by a few risk studies (e.g. Van Duinen et al. 2015, 2016; Hailegiorgis et al. 2018, Keshavarz and Karami  
512 2016, and Pouladi et al. 2019). ~~These studies –which have also–~~ implemented empirically supported and complex  
513 behavioural theories in ABMs similarly to ADOPT (Schriecks et al. 2021; Jager, 2021; Taberna et al., 2020;  
514 Waldman et al., 2020).

515 ADOPT differs from these models, however, through its specific aim to evaluate households and community  
516 drought disaster risk beyond the number of measures adopted, crop yield, or water use. Rarely (except e.g., Dobbie  
517 et al 2018) do innovation diffusion ABM use socio-economic metrics to evaluate drought impacts over time –  
518 while such risk proxies are of great social relevance. Another novel aspect of the ADOPT model is the evaluation  
519 of drought impacts . See also– ~~As such, ADOPT evaluates the heterogeneous changes in drought risk for farm~~

520 households, influenced by potential top-down drought disaster risk reduction (DRR) interventions. It does so  
521 through simulating their influence on individual bottom-up drought adaptation decisions by these farm households  
522 and their effect on socio-economic proxies for drought risk (poverty rate, food security and aid needs). To our  
523 knowledge, this is rather novel in the field of DRR and drought risk assessments.

#### 524 **5.4 Uncertainties in ADOPT and limitations in investigated measures and interventions**

525 ~~The initial ADOPT model setup was created through interviews with stakeholders~~ While, yield data has been  
526 validated over the historical period (Wens et al. 2020), ~~and the adaptive behaviour was based on empirical~~  
527 ~~household data (Wens et al. 2021).~~ Still, the model output cannot be used as a predicting tool. This would require  
528 more extensive validations for which, currently, data is not available. (For example Such data would include  
529 longitudinal information on household vulnerability and adaptation choices from areas where certain policies are  
530 being implemented, or detailed data on aid needs for the case study area). The past average poverty and food  
531 insecurity rates matched observations (Wens et al. 2020), ~~but~~ However, absolute amounts of emergency aid  
532 needs are sensitive to the averages and fluctuations of household assets which proved harder to verify. Besides,  
533 ~~p, and p~~overty and food insecurity depend also on external, food or labour market and other influences which  
534 might change towards the future. ~~Moreover~~ Besides, the ~~probability of the~~ simulated climate scenarios are not  
535 entirely realistic (because variability changes are ignored and because the synthetic future data is created based  
536 on statistics rather than physical climate and weather system changes)unknown. Moreover, ~~as~~ the East African  
537 Climate Paradox (Funk et al., 2021) creates its own set of challenges predicting future weather conditions in the  
538 study area. ~~Yet, the relative differences in the risk indicators are informative for the comparison of government~~  
539 ~~interventions under different potential future climates.~~

540 ~~Undoubtedly~~ Unavoidably, multiple possible smallholder adaptation measures are omitted in this study. ~~For~~  
541 ~~example,~~ many ~~other more~~ agricultural water management measures, agronomic ~~measures~~ actions, and other  
542 options under the umbrella of and other climate-smart agriculture, ~~at water management options~~ exist. Besides,  
543 only four different ~~(non)governmental policy~~ interventions are evaluated while various other exists. Costs of  
544 ~~these top-down government~~ interventions are unknown, making cost-benefit estimates regarding drought risk  
545 reduction strategies not possible for this study. ~~Also only a small set of potential future climates are evaluated, no~~  
546 ~~full set linked with probabilities is evaluated. While all of~~ Studying additional measures or interventions ~~these~~  
547 ~~would is~~ be possible using the ADOPT model, ~~they but~~ requires (the collection of) more data for parametrization  
548 and calibration.

549 Another future improvement to the model could be to directly sample the empirical household survey data (Wens  
550 et al 2020) to create a synthetic agent set. Now, the creation of agents (households) with different characteristics  
551 is drawn from distribution functions based on frequencies in the empirical data. Such one-to-one data-driven  
552 approach is similar to microsimulation and gaining popularity among ABMs (Hassan et al 2010). Lastly, the  
553 model application does assume no shifts in the processes underlying weather and human decision making: both  
554 the synthetic future weather situation and the decision making processes are based on past observations. To avoid  
555 the effect of systemic changes and black swan effect, only 30 “future” years are modelled.

556 Because ~~the model setup could not be fully validated, and scenarios results of the future scenario runs cannot be~~  
557 ~~falsified or verified~~ do not provide a complete overview of all possibilities, this study ~~does not~~ claims ~~not~~ to  
558 provide a prediction of the future for south-eastern Kenya. ~~However, ADOPT is meant to – rather than forecast~~  
559 ~~drought impact - increase understanding of the differentiated effect of adaptation policies: the relative differences~~  
560 ~~in the risk indicators are informative for the comparison of these top-down interventions under different changes~~  
561 ~~in temperature and precipitation. This study~~ ~~Rather, it~~ showcases the application of ADOPT as a decision support  
562 tool. ~~It-while~~ ~~evaluates~~ ~~ing~~ the robustness of a few, dedicatedly chosen ~~(non-)governmental~~ policy interventions  
563 on ~~farm household drought risk~~ ~~adaptation measures~~ under climate scenarios that are deemed to be relevant for  
564 the specific area. Future research can use ADOPT to study the differentiated effect of these interventions on  
565 different types of households, in order to tailor strategies and target the right beneficiaries of government  
566 interventions. .

567 **6. Conclusion**

568 ~~To increase the resilience of smallholder farmers to droughts, (non-)governmental~~~~Top-~~~~interventions~~~~down~~  
569 ~~interventions, providing drought and adaptation information as well as supporting the capacity to act on the basis~~  
570 ~~of this information, might be needed to alleviate barriers to adaptation, increasing farmers' intention to adopt~~  
571 ~~drought adaptation measures~~~~are needed to increase the resilience of smallholder farmers to current and future~~  
572 ~~drought risk.~~ However, to which extent these interventions will steer farmers' intention to adopt drought  
573 adaptation measures~~adaptive behaviour~~, hence how effective they are in reducing the farm household drought  
574 risk, often remains unknown. ~~The agent-based drought risk model ADOPT is used to evaluate the effectivity and~~  
575 ~~robustness of various (non-)governmental interventions under different climate change scenarios. ADOPT~~  
576 ~~captures the feedbacks between agricultural water management decisions by smallholder farmers and seasonal~~  
577 ~~weather conditions, and explicitly models adoption constraints and social interactions among farmers.~~

578 In this study, the agent-based drought risk adaptation model ADOPT is applied to evaluate the effect of potential  
579 future scenarios regarding climate change and ~~(non-)governmental~~policy interventions on agricultural drought  
580 risk in south-eastern Kenya. The smallholder farmers in this region face barriers to adopt drought adaptation  
581 measures such as mulching, ~~fanya~~Fanya juu terraces, shallow wells, and drip irrigation, to stabilize production  
582 and income. ADOPT simulates their adaptive behaviour, influenced by drought occurrences under changing  
583 climate conditions. ~~Adaptive behaviour is also, and~~ influenced by top-down (non-)government drought risk  
584 reduction interventions such as the introduction of ex-ante cash transfers, affordable credit schemes, improved  
585 early warning systems and tailored extension services, ~~which results in a changing individual and community~~  
586 ~~drought risk over time.~~

587 ~~We~~We show demonstrate that ~~all the~~ investigated interventions ~~have a positive effect~~ all increase on the uptake  
588 of adaptation measures as compared to the reactive scenario under no climate change (business-as-usual) by xx  
589 to xx pp., ~~reducing the drought related shocks in maize production and increasing the average yields, thus~~  
590 ~~reducing the need for external food aid.~~ Extension services (+27% uptake) multiply adaptation knowledge and  
591 thus increase self-efficacy among the smallholders, which increase raises the adoption of low cost, unknown less  
592 popular drought adaptation measures. Accessible c-while credit schemes (+30% uptake), alleviating a financial  
593 barrier, are useful-effective especially for more expensive cost-effective but expensive drought adaptation  
594 measures. Early warning systems (+22% uptake), creating risk awareness, are more effective in climate scenarios  
595 with less frequent drought if used as a tool to create awareness and risk perception. Ex-ante cash transfers (+25%  
596 uptake) allow the least endowed households to climb out of the poverty trap by adopting low-cost popular drought  
597 adaptation measures and thus reducing future shocks. The effect of climate change on the adoption of adaptation  
598 measures is limited. ~~Early warning systems are more effective in climate scenarios with less frequent drought if~~  
599 ~~used as a tool to create awareness and risk perception.~~

600 ~~An increased uptake of adaptation measures by smallholder farmers can offset a potentially harmful drying~~  
601 ~~climate trend~~Moreover, t, but this study shows-proves that alleviating only one barrier to adoption has a limited  
602 result on the ~~resilienee~~drought risk of the farm households. Under the pro-active scenario (+40% uptake),  
603 combining early warning with ex-ante cash transfers, smallholder farmers are better supported to adopt drought

604 adaptation measures and to create, on average, more wealth. However the effect of climate change on farm  
605 households risk differs significant under this proactive scenario. While for wetter conditions, this scenario is able  
606 to increase food security and reduce poverty, this is not sufficient to diminish the need for external food aid under  
607 every evaluated climate scenario. Only by combining all four interventions (+139% uptake), a strong increase in  
608 the adoption of measures is estimated. S~~simultaneously~~ increasing risk perception, reducing investment costs, and  
609 elevating self-efficacy, creates nonlinear synergies ~~arise resulting in a strong increase in the adoption of measures.~~  
610 Under such ~~strategie~~prospective government approach, ADOPT ~~estimates~~ implies significantly reduced food  
611 insecurity, decreased poverty levels, and drastically lower drought emergency aid needs after 10 to 20 years,  
612 under all investigated climate change scenarios.

613 This study ~~proves~~ suggests that, in order to ~~achieve~~ reach the current targets of the Sendai Framework for Disaster  
614 Risk, which aims at building a culture of resilience, and to ~~a~~ achieve Sustainable Development Goals “zero  
615 hunger”, “sustainable water management” and “climate resilience”, a holistic approach is needed. While we  
616 present a proof-of-concept rather than predictive model, the results improve the understanding of future  
617 agricultural drought disaster risk under socio-economic, policy and climate trends. We provide evidence that  
618 agent-based models such as ADOPT can serve as decision support tools to tailor drought risk reduction  
619 interventions under uncertain future climate conditions: ~~combining~~ More research into the heterogeneous effect  
620 of the investigated top-down interventions on households’ adaptation decisions and drought risk can provide  
621 information for the effective and efficient tailoring of the policy interventions. However, from this study, it is  
622 clear that m~~ultiple~~ interventions is needed now - both (risk and adaptation) information provision and the  
623 creation of action perspective - should be combined to build a sustainable future for smallholder farmers in  
624 Kenya’s drylands. ~~Besides, it provides evidence that agent based models such as ADOPT can serve as decision~~  
625 ~~support tools to tailor drought risk reduction interventions under uncertain future climate conditions.~~

Outline	ADOPT Model description
I.i Purpose	<p><i>What is the purpose of the study?</i> The purpose of this study is evaluating the effect of possible climate change and (non-)governmental policies on drought risk of smallholder farmers. The ADOPT model is capable of simulating the farm conditions and adaptation decisions of these farm households, and designed to include different climate and policy scenarios and their effect on the livelihoods of these last. : The model is designed to disentangle complex adaptive behaviour in an agricultural drought risk context. The multi-disciplinary modelling approach is rooted in quantitative socio hydrology framework', where the human system both influences and adapts to the changing physical agricultural drought environment, and adopts an agent-based approach to deal with heterogeneity in adaptive behaviour of smallholder households. Understanding the two way feedback between households' adaptation decisions and maize yield losses over time will help optimize future drought impact estimations and allow for the testing of drought management policies</p> <p><i>For whom is the model designed?</i> The adopt model can allow scientists to increase understanding of the socio hydrological reality of drought risk and drought adaptation, while it can help decision makers to design drought policies that target the right farm household and evaluate their effect on their drought vulnerability.</p>
I.ii Entities, state variables, and scales	<p><i>What kinds of entities are in the model?</i> The agents in ADOPT are individual farm households that have a farm of varying size and potentially an off farm income source. Farm households are connected to their neighbours in a network setting, ADOPT runs on the farm scale, modelling yield per household farm.</p> <p><i>By what attributes are these entities characterized?</i> Farm households have, other than a farm with a specific farm size, a family size; a household head (male/female), a stock of assets, income sources and farm experience. Household heads have a memory regarding past drought impacts, have a perception about their own capacity and in varying degrees, have information about potential adaptation measures.</p> <p>Farms, belonging to households, are assumed to be producing maize under certain fixed and changing water management conditions. They are exposed to daily weather conditions and produce maize harvest twice a year.</p> <p><i>What are the exogenous factors of the model?</i> Two exogenous factors influence the farm household systems: climate change and (non-)governmental policies. The first alter the frequency of droughts—potential failed crop yields—while the latter affects the knowledge, access to credit and risk perception of households who are recipient of the policies.</p> <p><i>How is space included in the model?</i> As the space is spatially implicit, all farm household farms receive the same amount of rain and sun, differentiating only in their size an management applied.</p> <p><i>What are the temporal resolution and extent of the model?</i> One time step of ADOPT represents one year. The crop model part runs on a daily basis, producing seasonal maize crop yield, but decisions by the farm households to eventually adopt new adaptation measures are only made in the long dry season, once every year. Each year, the poverty status, food security situation and potential food aid needs of all farm households are evaluated. The model runs 30 years historic baseline and 30 scenario years.</p>

	I.iii Process overview and scheduling	<i>What entity does what, and in what order?</i> The farm income (harvest)—whether or not affected by a drought—influences the annual income of the farm household; the household head decides—based on her/his memory of past droughts, on the knowledge through her/his network and its own capacity, whether or not he/she want and is able to adopt a new drought adaptation measure. The decision to adopt a new measures changes the farm management of the next years, hence crop yields for the following seasons.
Design Concepts	H.i Theoretical and Empirical Background	<i>Which general concepts, theories or hypotheses are underlying the model's design at the system level or at the level(s) of the submodel(s) ?</i> The crop water model assumes that, with knowing the soil and crop characteristics and the farm management practices, crop yield can be predicted based on the weather conditions. The FAO crop water model, simulates the daily growth of biomass /roots of crops
		<i>On what assumptions is/are the agents' decision model(s) based?</i> The PROTECTION MOTIVATION THEORY has been applied to predict and understand protective behaviour (Rogers 1983). PMT consists of two underlying cognitive mediating processes that cause individuals to adopt protective behaviors when faced with a hazard (Rogers 1983; Rogers and Prentice Dunn 1997). These are the Risk appraisal process forming a risk perception and the coping appraisal process forming a perception of the adaptation efficacy.
		<i>Why is a/are certain decision model(s) chosen?</i> Analysis of the past and intended behaviour of farm households in the region (Wens 2021?) provided support for the choice of theory, but also showed the need to include network influencing risk perception and capacity of the households. Besides helping to parameterize the model, it also helped to calibrate the influence of the different factors affecting the decision making process of the farm household. Showing the effect of different assumptions about decision making in Wens et al 2020, and with empiric evidence on the adaptive behaviour (Wens 2021), the decision rules in ADOPT are assumed be a good enough representation of the processes that matters in the decision making on drought adaptation.
		<i>If the model / a submodel (e.g. the decision model) is based on empirical data, where does the data come from?</i> ADOPT is calibrated with data from existing longitudinal household surveys (TEGEMEO 2000 2004 2007 2010) and from a fuzzy cognitive map of key informants, and a semi structured household questionnaire among 260 smallholder farmers (Wens 2018, 2019, 2021)

<p>H.ii Individual Decision Making</p>	<p><i>What are the subjects and objects of decision making? On which level of aggregation is decision making modeled? Are multiple levels of decision making included? What is the basic rationality behind agents' decision making in the model? Do agents pursue an explicit objective or have other success criteria? How do agents make their decisions? Do the agents adapt their behavior to changing endogenous and exogenous state variables? And if yes, how?</i></p> <p>In ADOPT, decision making is coded assuming complex behaviour of individual farm households. Factors influencing the adoption of drought adaptation measures can generally be categorized into extrinsic factors and intrinsic factors. Extrinsic factors include the social and natural environment in which households exists. This steers a households' perception of the drought risks they face (Risk Appraisal). For example, experiences of historic droughts affects individuals' evaluation of drought risk leading to a biased drought risk judgement (e.g. Singh and Chudasama 2017; Keshavarz &amp; Karami 2014). Generally, more vulnerable households have greater risk perceptions (van Duinen et al. 2016). Besides, access to extension services (field demonstrations, farmer trainings) used as primary source of information by 30%, and other sources of information sharing (i.e. through the social network (18%) or NGOs (10%)) can have profound effect on whether or not individuals take proactive action (Kitinya et al., 2012; Shikuku, 2017; Haer et al. 2016). Also age, gender and education can play a role (Burton 2014)</p> <p>Knowing the risk and knowing how to or being able to respond to the risk are not the same, as one should believe a measure will be effective, be convinced that one has the ability to implement the measure and be able to pay reasonable costs (Van duinen). Financial or knowledge constraints may limit economic rational decisions. Also the perceived ability to do something (Coping Appraisal) influences the decision making process (Esner 2012, Eiser 2012). This coping appraisal can be subject to intrinsic factors such as education level, sources of income, farm size, family size, gender, confidence and beliefs, risk-aversion, and age (Shikuku, 2017; Okumu, 2013; Eisner 2012, Van duinen, Dang et al 2014; Zhang et al 2019). In order to understand the observed adaptive behaviour of Kenya's smallholder households, it is critical to incorporate such social economic factors in the decision making framework of drought adaptation models (Van duinen et al 2015; Keshavarz &amp; Karami 2014; SRezael salmani 2017; ingh and Chudasama 2017; O'Brien et al., 2006; Maddison, 2007; Adger et al., 2009; Jones and Boyd, 2011; Ialani et al 2016; Maddison 2007; Gbet-ibouo 2009; Deressa et al. 2011; Mandleni and Anim 2011; Wheeler et al. 2013; Gebrehiwot van der veen, Keshavarsz 2016).</p>
<p>H.iii Learning</p>	<p><i>Is individual learning included in the decision process? How do individuals change their decision rules over time as consequence of their experience?</i></p> <p>Often, initial decisions, made by a few, can grow into large collective interventions, either through government incentive or social networks (Willy et al 2013, Ertsen et al., 2013; Holman et al., 2018). In ADOPT, households interact with their neighbours through traditional forms of labour exchange, cooperatives, pioneer households' and family ties; shaping risk awareness and response attitude (Okumu 2013, Shikuku 2017, Nkatha 2017). Such group membership can enhance social learning and knowledge spill over which influences people's adaptation intention and choice of specific measures (Tongruksawattana 2014; Below et al 2010). In the model, this translates to individual risk perception changing in the direction of the mean risk perception within individuals' social network (Haer?). Besides, households that do not regularly receive extension services, are limited to only implement measures that more than 2 of their neighbours have installed</p>

H.iv Individual Sensing	<i>What endogenous and exogenous state variables are individuals assumed to sense and consider in their decisions? Is the sensing process erroneous? Following the socio-hydrologic setup of the model, households with bounded rational behaviour are embedded in and interact with their social and natural environment. Changes in rainfall patterns during growing season will change households' risk perception; drought memory will influence the adaptive behaviour of these households.</i>
	<i>What state variables of which other individuals can an individual perceive? Households are aware of their assets, past yields, income sources and their stability, and household food needs. Households know their own but also their neighbours current yields and management practices.</i>
	<i>What is the spatial scale of sensing? Individual sensing happens on household level, but the model also produces overall statistics; like the average or median yield, the percentage of households in poverty or the total amount of food needed to cover all shortages.</i>
	<i>Are the mechanisms by which agents obtain information modeled explicitly, or are individuals simply assumed to know these variables? Sensing happens locally and households have a simulated "contact" with the farmers in their network to exchange info on risk and yields.</i>
H.v Individual Prediction	<i>Which data does the agent use to predict future conditions? By extrapolating from historic yield experiences, farmers have an expected yield every year.</i>
	<i>What internal models are agents assumed to use to estimate future conditions or consequences of their decisions? Households receiving extension services have the capacity to predict the average yield gain of adopting a new adaptation measure, which will influence their coping appraisal.</i>
	<i>Might agents be erroneous in the prediction process, and how is it implemented? Households without this access to training will predict the yield gain based on the extra yield of their neighbours with the considered adaptation measure.</i>
H.vi Interaction	<i>Are interactions among agents and entities assumed as direct or indirect? Smallholder households learn from the other households in their social network about the implementation and benefits of drought adaptation measure through pioneer households' and family ties (Below et al 2010; Shikuku 2017). In ADOPT, social interaction is explicitly modelled. Interventions with neighbours shape risk perception—the individual perception moves in the direction of the social network average—and also shape response attitude—households with no access to extension can only adopt measures already implemented by neighbours.</i>
	<i>On what do the interactions depend? Spatial distance (neighbourhood) is the main driver for networks; it is assumed a farmer cannot have more than 30 other farmers in her/his close, influential network, and it is assumed that s(he) would not walk more than 5km to reach persons in her/his network.</i>
H.vii Collectives	<i>Do the individuals form or belong to aggregations that affect, and are affected by, the individuals? Households are either more self-oriented, discussing matter with 10 neighbours, or group-oriented, sharing knowledge within a group / collective of 30 neighbouring households. Group membership (traditional forms of labour exchange, cooperatives, ...) can enhance social learning and knowledge spill-over; Often, initial decisions, made by a few, can grow into large collective interventions, either through government incentive or social networks (Ertsen et al., 2013; Holman et al., 2018).</i>
	<i>How are collectives represented? Group membership and network size are set at the initialization phase and do not change over time.</i>
H.viii Heterogeneity	<i>Are the agents heterogeneous? Household agents are heterogeneous in terms of state variables (i.e. farm size, household size, assets), and agent categorization (certain knowledgeable or uncertain) (Shikuku 2017, Asfaw et al 2012).</i>

		<p>Are the agents heterogeneous in their decision-making? Households can be inclined to adopt new technology or can be conservative (attitude towards change). Okumu (2013), Shikuku (2017) among others found that state variables such as age, gender, education of the household head and the household size have significant effects on this risk attitude.</p>
	<p>H.ix Stochasticity H.x Observation</p>	<p>What processes (including initialization) are modeled by assuming they are random or partly random? During the initialization, the household attribute values are derived stochastically within the uncertainty range values based on the survey data. For every subsequent time loop of the simulation, a random number between 0-1 is drawn for each household; if this is lower than their adaptation intention (also between 0-1) and the household is able to pay for the measure; then the household adopts it. This way, we account for non included factors introducing uncertainty in adaptive behaviour such as beliefs, physical health, ambitiousness etc. of the households. Moreover, also a stochastic perturbation is added to the Maize yield per farm as calculated through AquaCrop this to include effects of pests and diseases on the income and food security of farming households.</p>
Details	<p>H.i Implementation Details</p>	<p>How has the model been implemented? The model is coded in R, which is able to link the two sub models in Netlogo (the adaptive behaviour sub model) and Matlab (AquaCropOS).</p>
	<p>H.ii Initialization</p>	<p>What is the initial state of the model world, i.e. at time <math>t=0</math> of a simulation run? At the initial stage, households and their characteristics are randomly created based on the mean and standard deviation derived from the household dataset.</p> <p>Is initialization always the same, or is it allowed to vary among simulations? The weather situation from 1980-2010 is used as initialization phase where households initialize their risk perception and coping appraisal in the.</p> <p>Are the initial values chosen arbitrarily or based on data? The initial setup values are based on reports / surveys from the area (Tegemeo Dataset 2000,2004,2007,2010, and own surveys from 2019 (250 farmers)). The socio-economic household characteristics are summarized in table A, while the bio-physical field characteristics are summarized in table B</p>
	<p>H.iii Input Data</p>	<p>Does the model use input from external sources such as data files or other models to represent processes that change over time? The setup of the model is a result of participatory concept mapping with researchers and students of SEKU University, technical advisors of Kitui County department of water, agriculture, livestock and fishing, experts from SASOL foundation and 5 pilot households that have example farms for agricultural extension. The input data for the decision model was obtained from a survey on agricultural drought risk to smallholders in the case study area (Wens, 2019). Survey data includes a short questionnaire among employees of the Kenyan national disaster coordination units (n=10), semi-structured expert interviews (n=8) with NGOs, governmental water authorities and pioneer farmers in the Kitui district in Kenya, and an in-depth questionnaire among 250 smallholder farmers in the central Kitui. Extra information is derived from a household surveys in 2000, 2004, 2007 and 2010, conducted by the Tegemeo Agricultural Policy Research Analysis (TARAA) Project of the Tegemeo Institute. The project collects comprehensive information on rural households including, among others, demographic information, information on agricultural practices, business and informal labour practices, decision making, household assets and consumption in different counties in Kenya. Besides, the model initialization draws heavily from reports of CIAT (Climate Smart Agriculture in Kenya), FAO (The economic lives of smallholder households), IFPRI and the government of Kenya (County integrated development plans), CCAFS (Baseline Survey Indicators for Makeni/Wote, Kenya.), and from research (characterization of Maize producing households in Machakos and Makeni Districts) of Muhamad et al. (2010).</p>

	<p>III.iv Submodels</p>	<p><i>What, in detail, are the submodels that represent the processes listed in 'Process overview and scheduling'? The FAO crop water model AquaCrop OS (coded in Matlab© by Tim Foster (Foster et al.)) calculates seasonal crop production, based on hydro-climatologic conditions provided by the climate data and based on the agricultural management of the households. The agent-based model in which farming households decide on their drought adaptation measures, is coded in Netlogo©, a language specialized in ABMs.</i></p> <p><i>How were submodels designed or chosen, and how were they parameterized and then tested? AquaCrop OS was applied following Ngetich and Omyo, who both analyzed and approved the functioning of this model to simulate maize yield under different climates in Kenya.</i></p>

640 **Table C: Crop parameters for maize AQUACROPOS in ADOPT**

641	<b>Value — Crop parameters for AquaCropOS</b>
642	3 : Crop Type (1 = Leafy vegetable, 2 = Root/tuber, 3 = Fruit/grain)
643	1 : Planting method (0 = Transplanted, 1 = Sown)
644	1 : Calendar Type (1 = Calendar days, 2 = Growing degree days)
645	0 : Convert calendar to GDD mode if inputs are given in calendar days (0 = No; 1 = Yes)
646	16/03 : Planting Date (dd/mm)
647	31/08 : Latest Harvest Date (dd/mm)
648	5 : Growing degree/Calendar days from sowing to emergence/transplant recovery
649	40 : Growing degree/Calendar days from sowing to maximum rooting
650	80 : Growing degree/Calendar days from sowing to senescence
651	90 : Growing degree/Calendar days from sowing to maturity
652	40 : Growing degree/Calendar days from sowing to start of yield formation
653	5 : Duration of flowering in growing degree/calendar days ( 999 for non fruit/grain crops)
654	65 : Duration of yield formation in growing degree/calendar days
655	3 : Growing degree-day calculation method
656	8 : Base temperature (degC) below which growth does not progress
657	30 : Upper temperature (degC) above which crop development no longer increases
658	1 : Pollination affected by heat stress (0 = No, 1 = Yes)
659	35 : Maximum air temperature (degC) above which pollination begins to fail
660	40 : Maximum air temperature (degC) at which pollination completely fails
661	1 : Pollination affected by cold stress (0 = No, 1 = Yes)
662	10 : Minimum air temperature (degC) below which pollination begins to fail
663	5 : Minimum air temperature (degC) at which pollination completely fails
664	1 : Transpiration affected by cold temperature stress (0 = No, 1 = Yes)
665	12 : Minimum growing degree days (degC/day) required for full crop transpiration potential
666	0 : Growing degree days (degC/day) at which no crop transpiration occurs
667	0.3 : Minimum effective rooting depth (m)
668	0.8 : Maximum rooting depth (m)
669	1.3 : Shape factor describing root expansion
670	0.0105 : Maximum root water extraction at top of the root zone (m <sup>3</sup> /m <sup>3</sup> /day)
671	0.0026 : Maximum root water extraction at the bottom of the root zone (m <sup>3</sup> /m <sup>3</sup> /day)

719 Appendix A: Description of the ADOPT model following the ODD+D protocol (Laatabi et al., 2018; Müller et al., 2013):

720 **I. Overview**

721 **I.i Purpose**

722 **What is the purpose of the model?**

723 The purpose of ADOPT is to improve agricultural drought disaster risk assessments by including the complex  
724 adaptive behaviour of smallholder farmers. The ADOPT model simulates the welfare (poverty level, food security  
725 & aid needs) of smallholder farm households over time as a function of climate effects on agricultural production,  
726 mitigated by implemented adaptation measures, and simulates the adoption of such measures as a function of  
727 economic, social and psychological household characteristics. Understanding the two-way feedback between  
728 households' adaptation decisions and maize yield losses over time can help optimize drought impact estimations  
729 under climate and policy changes. ADOPT can be used to evaluate the adoption rate of adaptation measures under  
730 different climate and policy scenarios hence contrast their effect on the drought disaster risk – approximated by  
731 food security and welfare - of smallholder farmers.

732 **For whom is the model designed?**

733 The ADOPT model can allow scientists to increase their understanding of the socio-hydrological reality of  
734 drought disaster risk and drought adaptation in a smallholder farming context. It can also help decision makers to  
735 design drought policies that target specific farm household and evaluate the effect of these policies on their  
736 drought vulnerability.

737 **I.ii Entities, state variables, and scales**

738 **What kinds of entities are in the model?**

739 The agents in ADOPT are individual farm households that have a farm of varying size and potentially an off-farm  
740 income source. Two other entities exist: the crop land (multiple fields) that yields maize production and is owned  
741 by the farm households, and the market (one) where maize is sold and bought.

742 **By what attributes are these entities characterized?**

743 Farm households (see UML, figure A.1) have a farm – characterised by its farm size and the adaptation measures  
744 implemented on it-. They also have a family size, a household head (male/female) with a certain age and education  
745 level, financial assets (wealth, expressed in USD), off-farm employment, and farm, food and other expenses.  
746 Household heads have a memory regarding past drought impacts, have a perception about their own capacity,  
747 and, in varying degrees, have information about potential adaptation measures.

748 Crop land (farms) (see UML, figure A.1), belonging to households, produce maize under changing weather  
749 conditions, influenced by potential adaptation measures affecting water management conditions. The market (see  
750 UML, figure A.1) is influenced by local production and consumption, which results in a variable maize price

751 depending on the balance between supply and demand. In the presented case study, we consider relatively isolated  
 752 areas, less subjected to globalized market systems: maize price is variable following the total amount of locally  
 753 produced maize to replicate the observed price volatility (with minimum and maximum prices derived from  
 754 FEWSnet) during years of reduced production.

755  
 756 **Figure A1. UML diagram**

757 **What are the exogenous factors / drivers of the model?**

758 Two exogenous factors influence the farm household systems: daily weather (influenced by gradual climate  
 759 change) and drought disaster risk reduction policies (top-down policy interventions supporting smallholder  
 760 farmers). The first factor might alter the frequency and severity of droughts – which may lead to failed crop yields,

761 while the latter affects the knowledge, access to credit, and risk perception of households who are recipient of the  
762 policies.

### 763 **How is space included in the model?**

764 ADOPT runs on the scale of farm fields (size adjusted to the case study area). On this field scale, agricultural  
765 water management decisions (adaptation) interact with rainfall variability (drought hazard). However, spatially-  
766 explicit fields are used only in the initialisation phase so neighbouring farms can be identified but does not play  
767 any further role: space is only represented in a spatially-implicit way, all farms (crop land) receive the same  
768 amount of rain and sun, have the same soil type with a similar slope and differ only in their farm size and  
769 management applied.

### 770 **What are the temporal resolution and extent of the model?**

771 One time step of ADOPT represents one year. The crop model part runs on a daily basis, producing maize crop  
772 yield in every cropping season, but decisions by the farm households to eventually adopt new adaptation measures  
773 are only made once a year. Each year, the poverty status, food security situation, and potential food aid needs of  
774 all farm households are evaluated. The model runs 30 years historical baseline (+ 10 initialisation years) and 30  
775 scenario years.

## 776 **Liii Process overview and scheduling**

### 777 **What entity does what, and in what order?**

778 Every year, farm income of the households is updated with the maize harvest sold at the current market price (see  
779 centre of the flowchart in Fig. A.2). This harvest depends on the farm size of the household, the maize yields  
780 (defined by AquacropOS) which may be affected by a drought potentially mitigated by implemented drought  
781 adaptation measures, and on the food needs of the own household (subsistence is prioritized over selling;  
782 household members can die or be born (stochastically determined, based on birth and mortality rates in the study  
783 area). This farm income, together with a potential (fixed) off farm income, and with farm-size-dependent farm  
784 expenses, family-size-dependent household expenses, and potentially extra food expenses (if the own production  
785 was not sufficient to fulfil household food needs), alters the assets of the farm household. The farm household's  
786 memory of drought impacts (risk perception) is updated, and they interact (in random order) with their network  
787 of neighbours exchanging information on adaptation measures.

788 Once a year, the household head decides whether they want to adopt a new drought adaptation measure. They  
789 make this decision based on their memory of past drought impacts, their perception of the adaptation costs, the  
790 knowledge on adaptation measures through their networks and training, and their perception of their own capacity.  
791 The adoption of a new measure changes the farm management of those farmers, directly changes their wealth  
792 (implementation costs) and the farm expenses for the following years (maintenance costs), and influences crop  
793 yield and crop vulnerability to drought – thus potential farm income - during the following years.

Figure A2: Flowchart showing process overview

797

798 **II. Design Concepts**

799 **II.i Theoretical and Empirical Background**

800 **Which general concepts, theories or hypotheses are underlying the model's design at the system level or at**  
801 **the level(s) of the sub-model(s) ?**

802 The multi-disciplinary modelling approach of ADOPT is rooted in socio-hydrology (Sivapalan et al., 2012),  
803 where the human system both influences and adapts to the changing physical environment (in this case agricultural  
804 drought), and applies an agent-based approach to deal with heterogeneity in adaptive behaviour of smallholder  
805 households.

806 The setup / design of the model (the drought disaster risk system) is a result of participatory concept mapping  
807 with researchers and students of SEKU University, technical advisors of Kitui County Department of Water,  
808 Agriculture, Livestock and Fishing, experts from SASOL foundation, and five pilot households that have example  
809 farms for agricultural extension. This information informed the decision context of ADOPT.

810 **On what assumptions is/are the agents' decision model(s) based?**

811 In the first design of ADOPT, three adaptive behaviour scenarios were analysed, with increasing complexity. A  
812 'business as usual' scenario with no changing drought adaptation measures was tested, characterizing the 'fixed  
813 adaptation' approach. The conventional Expected Utility Theory (von Neumann and Morgenstern, 1944)  
814 represents the widely-used economist assessment of choice under risk and uncertainty. Simulating bounded  
815 rational rather than economic rational adaptation decisions, the Protection Motivation Theory (Rogers, 1983) is  
816 used as a way to include psychological factors in the heterogeneous adaptive behaviour of smallholders.

817 Indeed, it is often stated that households' adaptive behaviour is bounded rational and embedded in the economic,  
818 technological, social, and climatic context of the farmer (Adger, 2006). Knowing the risk is not enough to adapt;  
819 farmers should also believe the adaptation measure will be effective, be convinced that they have the ability to  
820 implement the measure, and be able to reasonably pay the costs (van Duinen et al., 2015b). Financial or knowledge  
821 constraints may limit economic rational decisions. Also age, gender and education – intrinsic factors - can play a  
822 role (Burton, 2014). The perceived ability to do something (Coping Appraisal) influences the decision making  
823 process(Eiser et al., 2012). This coping appraisal can be subject to intrinsic factors such as education level, sources  
824 of income, farm size, family size, gender, confidence and beliefs, risk-aversion, and age (Le Dang et al., 2014;  
825 Okumu, 2013; Shikuku et al., 2017; Zhang et al., 2019).

826 In order to understand the observed adaptive behaviour of smallholder households, it is critical to incorporate  
827 such social-economic factors in the decision-making framework of drought adaptation models (Bryan et al., 2009,  
828 2013; Deressa et al., 2009; Gbetibouo, 2009; Gebrehiwot & van der Veen, 2015; Keshavarz & Karami, 2016;  
829 Lalani et al., 2016; Mandleni & Anim, 2011; O'BRIEN et al., 2007; Rezaei et al., 2017; Singh & Chudasama,  
830 2017; van Duinen et al., 2015b, 2015a, 2016; Wheeler et al., 2013). After we had promising results running  
831 ADOPT with the bounded rational scenario, it is assumed that farmers show a bounded rationality in the further  
832 application of ADOPT.

833 **Why is a/are certain decision model(s) chosen?**

834 Analysis of the past and intended behaviour of farm households in the region provided support for the choice of  
835 theory, but also showed the need to include network influencing risk perception and capacity of the households.  
836 Besides helping to parameterize the model, it also helped to calibrate the influence of the different factors affecting  
837 the decision making process of the farm household. Showing the effect of different assumptions about decision  
838 making in the first exploration of ADOPT (M. Wens et al., 2020), and with empiric evidence on the adaptive  
839 behaviour (M. L. K. Wens et al., 2021), the decision rules in ADOPT are assumed be a good enough representation  
840 of the decision making process regarding drought adaptation.

841 **If the model / a sub-model (e.g., the decision model) is based on empirical data, where does the data come**  
842 **from?**

843 ADOPT is designed/initialised with data from existing longitudinal household surveys (Tegemeo Institute, 2000,  
844 2004, 2007, 2010) and from a fuzzy cognitive map of key informants, and parameterized/partially calibrated with  
845 data from a semi-structured household questionnaire among 260 smallholder farmers Survey reports can be found  
846 here:

847 - <https://research.vu.nl/en/publications/survey-report-kitui-kenya-expert-evaluation-of-model-setup-and-pr>

848 - <https://research.vu.nl/en/publications/survey-report-kitui-kenya-results-of-a-questionnaire-regardings-us>

849 **At which level of aggregation were the data available?**

850 Data from the surveys are available on individual household level.

851 **II.ii Individual Decision Making**

852 **What are the subjects and objects of decision-making? On which level of aggregation is decision-making**  
853 **modelled?**

854 In ADOPT, individual farm households make individual adaptation decisions about their farm water management  
855 (in the case study in Kenya: mulching, Fanya Juu terraces, drip irrigation or shallow well) to reduce their  
856 production vulnerability to droughts. There are no multiple levels of decision making included.

857 **What is the basic rationality behind agents' decision-making in the model? Do agents pursue an explicit**  
858 **objective or have other success criteria?**

859 Farmers generally try to reduce their drought disaster risk (achieve food security, evade poverty and avoid needing  
860 emergency aid) and thus try to maximise crop yields (diminish yield reduction under water-limited conditions)  
861 given the capacity they have to adopt adaptation measures.

862 **How do agents make their decisions?**

863 The Protection Motivation Theory (Maddux & Rogers, 1983) (see II.i) is used to explain the decision making  
864 process of the households. PMT consists of two underlying cognitive mediating processes that cause individuals  
865 to adopt protective behaviours when faced with a hazard (Floyd et al., 2000): It suggests that the intention to

protect (in this study, the farmers' intention to adopt a new adaptation measure) is motivated by a persons' risk appraisal and the perceived options to cope with risks. The former depends on, for example, farmers' risk perception, on their own experiences with drought disasters and memory thereof, and on experiences of risk events in their social networks. The latter is related to different factors such as perceived self-efficacy (i.e. assets and sources of income, education level, and family size), adaptation efficacy (land size, adaptation measure characteristics) and adaptation costs (expenses in relation to their income) (Gebrehiwot & van der Veen, 2015; Keshavarz & Karami, 2016; van Duinen et al., 2015, 2016a). Households do not have any other objective or success criteria. A detailed description of how PMT is modelled – including the sensitivity analysis regarding the relative weights of the PMT factors - can be found in Wens et al. (2019): In ADOPT, farm households develop an intention to adapt (protect) for each potential adaptation measure (m) which changes every year (t). If a household has the financial capacity to pay for a considered measure (Stefanovi, 2015), the intention to adapt is translated into the likelihood the household will adopt this measure in the following years. (This can be influenced by having access to credit.) The actual adoption is stochastically derived from this likelihood to adopt a measure.

$$IntentionToAdapt_{t,m} = \alpha * RiskAppraisal_t + \beta * CopingAppraisal_{t,m}$$

Although Stefanovi (2015), Van Duinen et al. (2015a), and Keshavarz and Karami (2016) have found positive relationships between the factors of PMT and observed protective behaviour, a level of uncertainty exists related to the relative importance of risk appraisal and coping appraisal in the specific context of smallholder households' adaptation decisions in semi-arid Kenya. Therefore, the  $\alpha$  and  $\beta$  parameters were introduced as weights for the two cognitive processes. To address the associated uncertainty, they were widely varied ( $\alpha, \beta \in [0.334:0.666]$ ) in a sensitivity analysis.

Risk appraisal is formed by combining the perceived risk probability and perceived risk severity, shaped by rational and emotional factors (Deressa et al., 2009, 2011; Van Duinen et al., 2015b). Whereas risk perception is based in part on past experiences, several studies have suggested that households place greater emphasis on recent harmful events (Gbetibouo, 2009; Rao et al., 2011; Eiser et al., 2012). To include this cognitive bias, risk appraisal is seen as a sort of subjective, personal drought disaster memory, defined as follows (Viglione et al., 2014):

$$RiskAppraisal_t = RiskAppraisal_{t-1} + (Drought_t * Damage_t) - 0.125 * RiskAppraisal_{t-1} \text{ with } Damage_t = 1 - \exp(-harvestloss_t)$$

The drought occurrence in year t is a binary value with a value of 1 if the SPEI-3 value falls below -1. The disaster damage of a household is related to their harvest loss during the drought year, which is defined as the difference between their current and average harvest over the last 10 years.

Coping Appraisal represents a households' subjective "ability to act to the costs of a drought adaptation measures, given the adaptation measures' efficiency in reducing risk" (Stefanovi, 2015; Van Duinen et al., 2015a). It is a combination of the households' self-efficacy, adaptation efficacy of the measure, and its adaptation costs:

$$CopingAppraisal_{t,m} = \gamma * SelfEfficacy_t + \delta * AdaptationEfficacy_{t,m} + \varepsilon * (1 - Adaptationcosts_t)$$

898

899 Although Stefanovi (2015), Van Duinen et al. (2015b), and Keshavarz and Karami (2016) quantified the  
 900 relationships between the factors driving the subjective coping appraisal of individuals, a level of uncertainty  
 901 remains related to the relative importance of these drivers in the context of smallholder households' adaptation  
 902 decisions in semi-arid Kenya. Therefore, weights ( $\gamma, \delta, \varepsilon \in [0.25:0.50]$ ) were introduced and varied in a sensitivity  
 903 analysis using different ADOPT model runs.

904 The Adaptation Costs of the possible measures are expressed in terms of a percentage of the households' assets.  
 905 The Adaptation Efficacy is calculated as the percentage of yield gain per measures compared to the current yield.  
 906 This can be influenced by access to extension services (which gives an objective yield gain based on future climate  
 907 rather than an estimate based on current practices of neighbours)

908 Self-efficacy is assumed to be influenced by education level (capacity), household size (labour force), age and  
 909 gender; all social factors found to influence risk aversion and adaptation decision (Oremo, 2013; Charles et al.,  
 910 2014; Tongruksawattana, 2014; Muriu et al., 2017).

911

912 **Do the agents adapt their behaviour to changing endogenous and exogenous state variables? And if yes,**  
 913 **how?**

914 Exogenous factors influencing adaptation decisions in ADOPT include the climate and the policy context in which  
 915 households exists. Drought (a feature of the climate context) induced crop losses steer a households' perception  
 916 of the drought disaster risks they face (Risk Appraisal). For example, experiences of historical droughts or  
 917 receiving early warnings about upcoming drought affects individuals' evaluation of drought disaster risk, leading  
 918 to a personal drought disaster risk judgement (e.g. Keshavarz et al., 2014; Singh & Chudasama, 2017). Besides,  
 919 access to extension services (a feature of the climate context) can have profound effect on whether or not  
 920 individuals take proactive action (Kitinya et al., 2012; Shikuku et al., 2017). Endogenous factors, as explained  
 921 above, include age, household size, education level, maize yield variability and assets (and the potential access to  
 922 credit market).

923 **Do spatial aspects play a role in the decision process?**

924 Farmer networks (connections with neighbours) exist, and information is passed through this social network.

925 **Do temporal aspects play a role in the decision process?**

926 Yes, risk memory is based on the crop yield variability of the accumulated past years and gives farm households  
 927 an expectation about the upcoming crop yield.

928 **Do social norms or cultural values play a role in the decision-making process?**

929 No (only implicitly included, see II.ix)

930 **To which extent and how is uncertainty included in the agents' decision rules ?**

931 No

932 **II.iii Learning**

933 **Is individual learning included in the decision process? How do individuals change their decision rules over**  
934 **time as consequence of their experience?**

935 Decision rules follow the PMT and are thus fixed, but some rules differ among type of households. Households  
936 that do not regularly receive extension services, are limited to only implement measures that their neighbours  
937 have installed as they are not aware of the existence of others. Besides, farmers who receive training will form  
938 their perception about the adaptation efficacy in a more objective way (as they have knowledge of average yield  
939 results under the adaptation measures while other farmers estimate this based on yield of their peers with such  
940 measure).

941 **Is collective learning implemented in the model?**

942 No

943 **II.iv Individual Sensing**

944 **What endogenous and exogenous state variables are individuals assumed to sense and consider in their**  
945 **decisions? Is the sensing process erroneous?**

946 Households are aware of their assets, past yields, income sources and their stability, and household food needs  
947 (Fig. A1). Following the socio-hydrologic setup of the model, households with bounded rational behaviour are  
948 embedded in and interact with their social and natural environment. Changes in rainfall patterns during the  
949 growing season will change households' risk perception through fluctuations in crop yield; drought memory will  
950 influence the adaptive behaviour of these households. Besides, there is a diffusion of technology due to  
951 interactions and knowledge exchanges among farm households as discussed above.

952 **What state variables of which other individuals can an individual perceive?**

953 Households know their own but also their neighbours' current yields and management practices. They make  
954 assumptions about the adaptation efficacy based on this.

955 **What is the spatial scale of sensing?**

956 Individual sensing happens on household level, but also through the individual social network that the farmers  
957 have, containing 3 to 30 other farmers.

958 Are the mechanisms by which agents obtain information modelled explicitly, or are individuals simply  
959 assumed to know these variables?

960 Households can get information about early warnings and through extension training. Households also have a  
961 simulated information transfer moment with the farmers in their neighbourhood to exchange information on risk  
962 and yields.

963 Are the costs for cognition and the costs for gathering information explicitly included in the model?

964 No

## 965 II.v Individual Prediction

966 Which data uses the agent to predict future conditions?

967 By extrapolating from historical yield experiences, farmers have expectations about their maize yield every year.  
968 If an early warning system is in place, farmers know about upcoming droughts that can influence their crop yield.

969 What internal models are agents assumed to use to estimate future conditions or consequences of their  
970 decisions?

971 Households receiving extension services have knowledge about the average (future) yield gain of adopting a new  
972 adaptation measure, which will influence their coping appraisal.

973 Might agents be erroneous in the prediction process, and how is it implemented?

974 Households without this access to training will predict the yield gain based on the extra yield of their neighbours  
975 who have already adopted the considered adaptation measure.

## 976 II.vi Interaction

977 Are interactions among agents and entities assumed as direct or indirect?

978 In ADOPT, households interact with their neighbours, shaping risk awareness and response attitude (Nkatha,  
979 2017; Okumu, 2013; van Duinen et al., 2016). Such networks can enhance social learning and knowledge spill  
980 over, which influences people's adaptation intention and choice of specific measures (Below et al., 2010;  
981 Tongruksawattana, 2014). Smallholder households learn from the other households in their social network about  
982 the implementation and benefits of drought adaptation measure through neighbouring households' (Below et al  
983 2010; Shikuku 2017). In ADOPT, exchanges with neighbours shape risk perception – the individual perception  
984 moves in the direction of the social network average – and also shape perceived adaptation effectivity. Moreover,  
985 households with no access to extension can only adopt measures already implemented by neighbours.

986 On what do the interactions depend?

987 Households are either more self-oriented, discussing matters with 10 neighbours, or group-oriented, sharing  
988 knowledge within a group / collective of 30 neighbouring households.

989 Spatial distance (neighbourhood) at initialisation is the key driver for networks; it is assumed that s(he) would  
990 not walk more than 5km to reach people in her/his network.

991 **If the interactions involve communication, how are such communications represented?**

992 Communication is not explicitly modelled.

993 **If a coordination network exists, how does it affect the agent behaviour? Is the structure of the network**  
994 **imposed or emergent?**

995 No coordination network exists.

## 996 **II.vii Collectives**

997 **Do the individuals form or belong to aggregations that affect, and are affected by, the individuals? How**  
998 **are collectives represented?**

999 No, no fixed collectives exist as the social networks the agents have, are individual in nature.

## 1000 **II.viii Heterogeneity**

1001 **Are the agents heterogeneous? If yes, which state variables and/or processes differ between the agents?**

1002 Household agents are heterogeneous in terms of state variables (i.e. farm size, household size, assets), and differ  
1003 in access to credit market, extension services and early warning beneficiaries, changing their adaptive behaviour  
1004 (Asfaw et al., 2017; Okumu, 2013; Shikuku et al., 2017)

1005 **Are the agents heterogeneous in their decision-making? If yes, which decision models or decision objects**  
1006 **differ between the agents?**

1007 Okumu (2013), Shikuku (2017), among others, found that state variables such as age, beliefs, gender, education  
1008 of the household head, and the household size have significant effects on their risk attitude. These factors are  
1009 included in the model application of the Protection Motivation Theory through the self-efficacy factor.

## 1010 **II.ix Stochasticity**

1011 **What processes (including initialization) are modelled by assuming they are random or partly random?**

1012 The likelihood to adopt a measure of a household is directly derived from the intention to adapt of the measure  
1013 with the highest intention for that household. This is stochastically transferred into an actual decision whether or  
1014 not to adopt the measure. For every time step of the simulation, a random number between 0-1 is drawn for each  
1015 household; if this is lower than their adaptation intention (also between 0-1) and the household is able to pay for  
1016 the measure, then the household adopts it. This probabilistic way of looking at adaptation intention and the  
1017 stochastic step to derive the actual decisions allow to account for non-included factors introducing uncertainty in  
1018 adaptive behaviour such as conservatism, social / cultural norms, physical health, ambitiousness etc. of the  
1019 households. Moreover, also a stochastic perturbation (multiplied with a random number with average 1 and SD

020 0.1) is added to the maize yield per farm as calculated through AquacropOS. This additional heterogeneity-  
021 inducing step is done to include effects of pests and diseases on the income and food security of farming  
022 households.

023 **II.x Observation**

024 **What data are collected from the ABM for testing, understanding and analysing it, and how and when are**  
025 **they collected?**

026 The adoption of adaptation measures and their effect on the total crop production (and food stock on the market)  
027 and individual household wealth are tracked over the simulated years.

028 **What key results, outputs or characteristics of the model are emerging from the individuals?**

029 Drought disaster risk (the annual average of impacts over the run period) - expressed in terms of average annual  
030 poverty rate, level of food security and total emergency aid needs - is emerging from the model. They are defined  
031 based on the socio-economic conditions of individual farm households.

032

033 **III. Details**

034 **III.i Implementation**

035 **How has the model been implemented?**

036 The model is coded in R, which is able to link the two sub models in Netlogo (the adaptive behaviour sub model)  
037 and MATLAB (AquacropOS).

038 **Is the model accessible, and if so, where?**

039 No(t) yet

040 **III.ii Initialization**

041 **What is the initial state of the model world, i.e., at time t=0 of a simulation run?**

042 At the initial stage, households and their characteristics are randomly created based on the mean and standard  
043 deviation (Table A1) derived from the household dataset, obtained from a survey on agricultural drought disaster  
044 risk with smallholders in the case study area (Wens, 2019). Income off farm is linearly related to the household  
045 size, education level and negatively related to the farm size. Food and non-food expenditures are linearly related  
046 to the household size. Farm expenditures are linearly related to the farm size.

047  
048 **Table A1: Initialisation parameters for farm households in ADOPT**

<b><u>Parameter</u></b>	<b><u>Explanation of initialization parameters for farm households</u></b>	<b><u>Value</u></b>
<b><u>Age</u></b>	<u>Age of the household head (based on Wens 2019)</u>	<u>42 +- 9</u>
<b><u>Edu</u></b>	<u>Years of education of the household head (based on Wens 2019)</u>	<u>6 +- 3</u>
<b><u>Sex</u></b>	<u>Gender of the household head (male 1, female 0)</u>	<u>0.66</u>
<b><u>HH-size</u></b>	<u>Family size of the households (people living under same roof) (Wens 2019)</u>	<u>6 +- 2.5</u>
<b><u>Assets</u></b>	<u>Household financial assets (USD) that can be spend (based on IFPRI 2012)</u>	<u>80% &lt; 100</u>
<b><u>Farm-size</u></b>	<u>Size of the farm (in hectare) used for planting crops (Wens 2019)</u>	<u>0.7 +- 0.6</u>
<b><u>Off-farm</u></b>	<u>Income from activities not on the own farm in USD (Wens 2019)</u>	<u>1200 +- 500</u>
<b><u>Food-needs</u></b>	<u>Kilogram of maize to fulfil daily caloric intake needs, per adult</u>	<u>125</u>
<b><u>Exp-farm</u></b>	<u>Farm expenditures made by the household (USD/hectare/year) (Wens 2019)</u>	<u>118 +- 146</u>
<b><u>Exp-food</u></b>	<u>Food expenditures made by the household (USD/year) (Wens 2019)</u>	<u>567 +- 655</u>
<b><u>Exp-nonf</u></b>	<u>Other expenditures made by the household (USD/year) (Wens 2019)</u>	<u>446 +- 500</u>
<b><u>Network</u></b>	<u>Neighbouring farmers creating the social network of the farmer</u>	<u>10-30</u>

050 **Is initialization always the same, or is it allowed to vary among simulations?**

051 In ADOPT, multiple climate change scenarios and policy scenarios were initialised – this changed the exogenous  
052 variables in the model. Moreover, each initialization creates another synthetic agent set based on the average  
053 household characteristics. Besides, a sensitivity analysis is done to evaluate assumptions on the relative weights  
054 of the PMT factors (II.ii). Each combination of climate and policy scenario is run 12 times (3 possible  $\alpha$ ; 4  
055 possible combinations of  $\gamma, \delta, \epsilon$ ) to account for the endogenous variability and uncertainty.

056 **Are initial values chosen arbitrarily or based on data?**

057 The initialisation values are based on observed household data. Survey data includes a short questionnaire among  
058 employees of the Kenyan national disaster coordination units (n=10), semi-structured expert interviews (n=8)  
059 with NGOs, governmental water authorities and pioneer farmers in the Kitui district in Kenya, and an in-depth  
060 questionnaire among 250 smallholder farmers in the central Kitui. Extra information is derived from household  
061 surveys of 2000, 2004, 2007 and 2010, conducted by the Tegemeo Agricultural Policy Research Analysis  
062 (TARAA) Project of the Tegemeo Institute. Besides, the model initialization draws heavily from reports of CIAT  
063 (CIAT & World Bank, 2015), FAO (Rapsomanikis, 2010), IFPRI (Erenstein et al., 2011) and the government of  
064 Kenya (Kitui County Integrated report 2013-2017, 2017), CCAFS (CCAFS, 2015), and from research (e.g.,  
065 Muhammad et al., 2010).

066 **III.iii Input Data**

067 **Does the model use input from external sources such as data files or other models to represent processes**  
068 **that change over time?**

069 The daily weather conditions from 1980-2010 (from CHIRPS and CFSR) is used as input time series; for the  
070 future climate scenarios, the same data but with temperature and/is used.

071 Besides, survey data on household behaviour and drought risk context are used. Raw reporting can be found in:

- 072 • Wens, M. (2019). Survey report Kitui, Kenya: Results of a questionnaire regarding subsistence  
073 farmers' drought risk and adaptation behaviour.  
074 <https://research.vu.nl/ws/portalfiles/portal/98864069/MissionRapport.pdf>
- 075 • Wens, M (2018) Survey report Kitui, Kenya: Expert evaluation of model setup and preparations of  
076 future fieldwork <https://research.vu.nl/ws/portalfiles/portal/98863978/MissionRapport2018.pdf>

077 **Where does data come from? How is it collected? What is the level of available data? How is it structured?**

078 Data (also discussed in Wens et al. 2021) is collected in the field using a multi-method data survey approach  
079 (key informant interviews, fuzzy cognitive map, household questionnaire and choice experiment). This data is  
080 used to design the model, to validate the use of PMT, to initialise the agent set and to calibrate model outputs.

081 **What are the variables, entities and classes available in data? What do they represent?**

082 A full set of behavioural factors were evaluated through the household questionnaire, and these were linked to  
083 their actual behaviour and to their behavioural intentions, as well as to the results of the choice experiment  
084 investigating future behaviour (Wens et al. 2021). Besides, socio-economic and farm characteristics were  
085 questioned.

086 **How are data selected to form the agent entities? How is agent population generated and synthesized?**

087 As discussed above, the data is used to create a representative set of agents. Household variable means and  
088 standard deviations were used to create distribution functions and a synthetic agent set was created based on  
089 random draws from these functions. Moreover, correlation between different variables were maintained.

090 **What are the relationships and patterns that exist in data?**

091 As discussed above, relationship between household income and household head education level or farm size  
092 exist. Next to correlations between socio-economic or agricultural characteristics, correlations between  
093 psychological factors and actual or prospective adaptation decisions were investigated and used to design the  
094 behavioural module of ADOPT.

095 **III.iv Sub-models**

096 **What, in detail, are the sub-models that represent the processes listed in ‘Process overview and**  
097 **scheduling’?**

098 The FAO crop-water model AquacropOS (coded in MATLAB© by Tim Foster (Foster et al., 2017)) calculates  
099 seasonal crop production, based on hydro-climatologic conditions provided by the climate data and based on the  
100 agricultural management of the households. The agent-based model in which farming households decide on their  
101 drought adaptation measures, is coded in Netlogo®, a language specialized in ABMs. This contains the -making-  
102 decision module, which is a model-application of the Protection Motivation theory as explained in section II.i.  
103 More detailed explanation about how this is done can be found in Wens et al 2020.

104 **How were sub models designed or chosen, and how were they parameterized and then tested?**

105 AquacropOS was applied parameterized and calibrated following Ngetich (2011) and Omyo (2015), who both  
106 analysed and approved the functioning of this model to simulate maize yield under different climates in Kenya.  
107 The decision sub-model is described above in the sections about decision-making and theoretical foundations  
108 (II.ii). A more detailed description can be found in Wens et al 2020.

109 **What are the model parameters, their dimensions and reference values?**

110 For AquacropOS, Table A3 and A4 give an overview of the parameters that are used. For the decision-making  
111 module, Table A2 gives an overview of the factors used.

113

**Table A2: Initialisation parameters for the behavioural module in ADOPT**

<b><u>Factor</u></b>	<b><u>Explanation of the PMT factors</u></b>
<b><u>Current Yield</u></b>	<u>Average yield of last 5 years</u>
<b><u>Potential Yield</u></b>	<u>Expected / perceived yield when adopting a new adaptation measure</u> <u>Either based on yield of neighbours with that measure or on training info</u>
<b><u>Adaptation costs</u></b>	<u>Perception of the costs of new measures as percentage of assets</u>
<b><u>Knowledge-measures</u></b>	<u>1 if attending trainings, else the percentage of people in network with measure</u>
<b><u>Risk perception</u></b>	<u>Drought memory, 1 if last harvest there was 0 yield, 0 if never impacted</u>
<b><u>Adaptation efficacy</u></b>	<u>Yield gain as percentage of current yield, based on potential yield</u>
<b><u>Self – efficacy</u></b>	<u>Belief in own capacity, based on gender, age, HH size and access to training</u>
<b><u>Adaptive capacity</u></b>	<u>Product of self-efficacy, adaptation efficacy and -1 * adaptation costs</u>
<b><u>Adaptation intention</u></b>	<u>Product of adaptive capacity and risk perception, 0 if one of the underlying factors is 0 or if assets are smaller than costs of measure</u>

114

115

**Table A3: Initialisation parameters for AquacropOS in ADOPT**

<b><u>Value</u></b>	<b><u>Explanation of calibration parameters for AquacropOSv6.0 maize</u></b>
<b><u>60 / 80</u></b>	<u>Curve number value under Fanya Juu bunds or under absence of such bunds</u>
<b><u>06</u></b>	<u>Bund height (m)</u>
<b><u>50</u></b>	<u>Area of surface covered by mulches (50%)</u>
<b><u>0.5</u></b>	<u>Soil evaporation adjustment factor due to effect of mulches</u>
<b><u>SMbased</u></b>	<u>Irrigation method</u>
<b><u>7 / 3</u></b>	<u>Interval irrigation in days under manual / automated irrigation</u>
<b><u>40</u></b>	<u>Soil moisture target (% of TAW below which irrigation is triggered)</u>
<b><u>12</u></b>	<u>Maximum irrigation depth (mm/day)</u>
<b><u>50 / 75</u></b>	<u>Application efficiency under manual / automated irrigation</u>
<b><u>50</u></b>	<u>Soil surface wetted by irrigation (%)</u>

116

**Table A4: Crop parameters for maize AQUACROPOS in ADOPT**

Value      Crop parameters for AquacropOS

3      : Crop Type (1 = Leafy vegetable, 2 = Root/tuber, 3 = Fruit/grain)

1      : Planting method (0 = Transplanted, 1 = Sown)

1      : Calendar Type (1 = Calendar days, 2 = Growing degree days)

0      : Convert calendar to GDD mode if inputs are given in calendar days (0 = No; 1 = Yes)

16/03    : Planting Date (dd/mm)

31/08    : Latest Harvest Date (dd/mm)

5      : Growing degree/Calendar days from sowing to emergence/transplant recovery

40      : Growing degree/Calendar days from sowing to maximum rooting

80      : Growing degree/Calendar days from sowing to senescence

90      : Growing degree/Calendar days from sowing to maturity

40      : Growing degree/Calendar days from sowing to start of yield formation

5      : Duration of flowering in growing degree/calendar days (-999 for non-fruit/grain crops)

65      : Duration of yield formation in growing degree/calendar days

3      : Growing degree day calculation method

8      : Base temperature (degC) below which growth does not progress

30      : Upper temperature (degC) above which crop development no longer increases

1      : Pollination affected by heat stress (0 = No, 1 = Yes)

35      : Maximum air temperature (degC) above which pollination begins to fail

40      : Maximum air temperature (degC) at which pollination completely fails

1      : Pollination affected by cold stress (0 = No, 1 = Yes)

10      : Minimum air temperature (degC) below which pollination begins to fail

5      : Minimum air temperature (degC) at which pollination completely fails

1      : Transpiration affected by cold temperature stress (0 = No, 1 = Yes)

12      : Minimum growing degree days (degC/day) required for full crop transpiration potential

0      : Growing degree days (degC/day) at which no crop transpiration occurs

0.3     : Minimum effective rooting depth (m)

0.8     : Maximum rooting depth (m)

1.3     : Shape factor describing root expansion

0.0105 : Maximum root water extraction at top of the root zone (m3/m3/day)

0.0026 : Maximum root water extraction at the bottom of the root zone (m3/m3/day)

6.5     : Soil surface area (cm2) covered by an individual seedling at 90% emergence

37000 : Number of plants per hectare

0.89    : Maximum canopy cover (fraction of soil cover)

0.1169 : Canopy decline coefficient (fraction per GDD/calendar day)

0.2213 : Canopy growth coefficient (fraction per GDD)

1.05    : Crop coefficient when canopy growth is complete but prior to senescence

0.3     : Decline of crop coefficient due to ageing (%/day)

33.7    : Water productivity normalized for ET0 and CO2 (g/m2)

100     : Adjustment of water productivity in yield formation stage (% of WP)

50     : Crop performance under elevated atmospheric CO2 concentration (%)

0.48    : Reference harvest index

0      : Possible increase of harvest index due to water stress before flowering (%)

7      : Coefficient describing positive impact on harvest index of restricted vegetative growth during yield formation

3      : Coefficient describing negative impact on harvest index of stomatal closure during yield formation

- 163 15 : Maximum allowable increase of harvest index above reference value
- 164 1 : Crop Determinacy (0 = Indeterminant, 1 = Determinant)
- 165 50 : Excess of potential fruits
- 166 0.02 : Upper soil water depletion threshold for water stress effects on affect canopy expansion
- 167 0.20 : Upper soil water depletion threshold for water stress effects on canopy stomatal control
- 168 0.69 : Upper soil water depletion threshold for water stress effects on canopy senescence
- 169 0.80 : Upper soil water depletion threshold for water stress effects on canopy pollination
- 170 0.35 : Lower soil water depletion threshold for water stress effects on canopy expansion
- 171 1 : Lower soil water depletion threshold for water stress effects on canopy stomatal control
- 172 1 : Lower soil water depletion threshold for water stress effects on canopy senescence
- 173 1 : Lower soil water depletion threshold for water stress effects on canopy pollination
- 174 1 : Shape factor describing water stress effects on canopy expansion
- 175 2.9 : Shape factor describing water stress effects on stomatal control
- 176 6 : Shape factor describing water stress effects on canopy senescence
- 177 2.7 : Shape factor describing water stress effects on pollination

Appendix B: Adoption rates of adaptation measures

1180 Table B1 Adoption ratio (in share of population) at run year 30 under different climate and intervention scenarios. Note that the model showed an adoption rate of 25% for mulch, 70% for ~~fanya~~Fanya juu, 9% for well and X% for irrigation at run year 0 (start of climate change and policy scenarios) .

<i>Mulch</i>	<del>No</del> ChangeNo Change	Wet	Wet Hot	Hot	Dry Hot	Dry
<i>Reactive</i>	50.2%	47.8%	45.6%	42.1%	35.9%	38.5%

**Figure B1: Total amount of measures adopted per 1000 initialized households under the reactive scenario, averaged over all runs. The shaded area indicates the uncertainty introduced by different model initialisations and by different relative importance of the PMT factors on the decisions of households. Year 0 initiates policy drought risk reduction interventions (indicated with different line colours).**

195

200

**Figure B2: Total amount of measures adopted per 1000 initialized households under the three intervention scenarios and three climate change scenarios, averaged over all runs. The shaded area indicates the uncertainty introduced by different model initialisations and by different relative importance of the PMT factors on the decisions of households. Year 0 initiates policy drought risk reduction interventions (indicated with different line colours).**

### **Author contribution**

M. W. took lead in model development, scenario development and writing the manuscript. T.V. assisted model development, A.v.L. assisted with manuscript writing and both contributed to the scenario development. J.A. was at the basis of the creative process of model setup, development and model application and contributed to the manuscript writing.

### 1205 **Competing interests**

The authors declare that they have no conflict of interest.

### **Acknowledgements**

1210 The authors would like to thank Dr Moses N. Mwangi, Prof. Mary Mburu, ~~Mr~~Mr. Mutinda Munguti and the entire Sasol staff, for their help in creating the model contexts, discussing the initial model setup and assisting with the data collection to calibrate the model. This research is made possible by the Netherlands Organization for Scientific Research VICI research project number 453-583 13-006 and European Research Council grants nos. 884442 and 948601.
