14 **1 Take stock of the situation**

15 Women constitute a minority in the geoscience professional environment (around 30%, e.g., UNESCO, 2015;  
16 Gonzales, 2019; Handley et al., 2020), and as a consequence, they are underrepresented in disaster risk reduction  
17 (DRR) planning. [After examining the Sendai framework documents and data outputs](#), Zaidi and Fordham (2021)  
18 pointed out that the Sendai Framework for Disaster Risk Reduction 2015–2030 (SFDRR) has failed to [effectively](#)  
19 [promote women and girls' inclusion in disaster policy](#)~~promote women and girls' inclusion in disaster policy effectively~~.  
20 In addition, it represents a missed opportunity to tackle gender-~~(even beyond female-male dichotomy)~~-based issues  
21 in DRR ([even beyond the female-male dichotomy](#)). Nevertheless, practical actions have been promoted and applied  
22 in several contexts with promising results, but often they only remain lessons learned in local ised environments (Zaidi  
23 and Fordham, 2021). Instead, the global gender gap index, which includes political empowerment, economic  
24 participation and opportunity, educational attainment, health, and survival, reveals that [the average distance completed](#)  
25 [to parity is at](#)-only 68% in 2019. Although the gap closing rate has constantly improved, it will take about 135.6 years  
26 to close it completely (WEF, 2021). These numbers do not yet account for 2020–2021 data, where the global pandemic  
27 has more strongly impacted women, their career, their opportunities, and their health in comparison with men (e.g.,  
28 Alon et al., 2020; Chandler et al., 2021; Yildirim and Eslen-Ziya, 2021).

29 Gender recognition and representation do not affect the sole career sphere or the policy and DRR agenda. They even  
30 impact our vision about gender and gender equity in the actions, behaviours, and intentions before, during and after  
31 natural hazards. ~~One example is the number and the location (referred to the journal and journal's focus) of gender~~  
32 ~~and disaster publications (it is easy to recognize after a quick search on the most common academic web engines and~~  
33 ~~on the few literatures review published). Based on our literature search and on available review papers Among the few~~  
34 ~~literatures consulted, it was easy to recognize that in-depth gender papers were critically considered in most~~  
35 ~~non-technical (related to natural hazards, disasters and risk) journals. Not only, Without going into much detail, for~~  
36 most disaster-related papers, gender ~~is was only merely~~ used as a dichotomous variable (usually together with a set of  
37 other socio-demographic variables) to test assessments and some model results, which are the ~~main central core of~~  
38 ~~the papers~~. When gender results in a significant variable, it is rarely contextualised with the vulnerability of women  
39 and men in the socio-cultural and political environment of the study site (exceptions are ~~an e.g., exception is Finucane~~  
40 ~~et al., (2000); Cvetkovic et al., (2018); and Mondino et al., (2021) in a minimum among part among very few others~~  
41 ~~in literature~~). Instead, stereotypical biological sex motivations are more often considered (e.g., women are more fragile  
42 during disaster occurrences because they are physically weaker vulnerable due to housekeeping and child-bearing  
43 responsibilities (Paradise, 2005; De Silva and Jayatilaka, 2014)). Gender as a social structure has a complex  
44 interaction both at the individual and communal levels (Risman, 2018), able to influence the capacity of communities  
45 to actively withstand the negative occurrence of natural hazards withstand the negative occurrence of natural hazards  
46 actively. In our opinion, if we fail failing to understand that, we fail in risk reduction strategies and effective planning.  
47 To this point, we recognise that gender is poorly investigated in DRR papers. It is much more considered in “non-  
48 technical” social sciences articles, which are more oriented to history, societies, and social behaviours in general.  
49 Thus Moreover, gender diversity is scarce poorly represented in the professional realm of opportunities sphere of natural  
50 hazards, reflecting not only in recognising and with consequences for managing vulnerabilities and career opportunities  
51 in but also in academic research.

52 Thus, despite the global gender gap index decreasing over the years, challenges to gender equity (e.g. reaching equal  
53 political power, economic participation, educational attainment) are still strongly perceived. Therefore, practical  
54 actions, solutions solutions, and strategies to close the gender gap must continue to be tested and researched, the  
55 actions' efficacy assessed, and their effects adequately monitored. In this 'invited perspective', we have put individuals  
56 identifying themselves with genders usually considered that are a minority in the field of natural hazards, i.e. female  
57 and non-binary genders, women at the centre of the discussion. We aim to concretely contribute to understanding the  
58 standpoint of women these minorities who are often underrepresented, unheard and poorly considered professionally  
59 and in DDR policy and practice. Thus, this perspective qualitatively explores a collection of 1221 opinions of  
60 individuals identifying themselves as female and one opinion of an individual identifying themselves as non-binary  
61 working in the broad field of natural hazards (in academia, in the industry, as practitioners or policymakers). The  
62 respondents are disproportionate towards the female gender; as a result, most of the issues and solutions proposed and  
63 discussed in the present paper revolve around the female gender. We have collected their views in April 2021 with an  
64 online self-administered survey via EU Survey.

65 The questionnaire was short and explorative, examining opinions on the challenges (Q1) related to natural hazards in  
66 general and those concerning (Q2) natural hazards and gender equity, plus (Q3) on the most urgent solutions to  
67 withstand gender inequities. The last question (Q4) asked for the respondent's gender-related challenges experienced  
68 during their career (or studies). Questions have been purposely developed following a general-to-local scale,  
69 narrowing down their general perspectives in natural hazards research and concluding with one's own experience. We  
70 have chosen open questions to let the professionals personally provide the most critical priority for action, related  
71 challenges, and solutions. We have categorised all the answers through qualitative text analysis ~~and, Each question~~  
72 ~~answer to the four questions has been analysed independently by the three authors, and a. Each response to the four~~  
73 ~~questions has been analysed independently by the three authors. A~~ final discussion allowed to assign all responses to  
74 definitive categories to the key concepts expressed. All categories are shown in Figure 1. The survey included some  
75 socio-demographic variables (profession, educational level, and country of residence) characterising the respondents.  
76 The data collection used a random approach, where only interested participants offered their time participating in the  
77 survey; we found a heterogeneous (and disproportionate) representation of those demographic categories. The survey  
78 was conducted in April 2021 online on EUSurvey, a service created and managed by the European Commission. The  
79 survey was fully anonymised, and no user-related data ~~have been were~~ saved. No respondent's sensitive information  
80 (e.g., name, ~~and~~ surname or age) was asked. The survey, i.e. link to the questionnaire with a short explanatory and  
81 motivational text, was advertised via email to the EGU NHESS author list and to a list of female professionals that  
82 the authors had collected in their networks. Moreover, the survey was advertised on social media, particularly on  
83 Twitter, LinkedIn, and Facebook, through the personal accounts of the first two authors.

84 Among 122 people who filled the questionnaire, 121 recognised themselves as female and ~~4 one~~ as non-binary. Since  
85 also non-binary people are underrepresented ~~voices~~, we decided to include their answers in the analysis. ~~Table 1~~  
86 summarises the demographics of the respondents. Individuals recognising themselves as male were excluded from the  
87 survey via a first barrier question about their gender. The sample is dominated by female, European scientists working  
88 on hydro-meteorological hazards or multi-hazards.

89 *Table 1. Summary of the respondents' demographics expressed in percentage.*

<b>Identified gender</b>	<b>Respondents [%]</b>
Female	99.2
Non-binary	0.8
<b>Natural Hazard field</b>

91 **2 The voices collected**

92 The responses to each of the four questions have been categorised into two groups: related to (i) natural hazards ([dark](#)  
93 [grey in Figure 1](#)) and (ii) professional development ([light grey in Figure 1](#)). This division is because respondents  
94 oriented their answers based on personal judgment, progressed professional experience, and cognitive and emotional  
95 background. In the following chapters, direct quotes of responses received are identified with ID and a sequential  
96 number (from 1 to 122 for each question). [The categories for each question and the related percentage of responses](#)  
97 [are also included in the Supplementary Material in the form of a Table.](#)

Q1: Challenges in NH	Q2: Gender equity challenges in NH	Q3: Gender equity solutions in NH	Q4: Personal experience
Lack of proper political management, provision of resources and funding	Lack of inclusivity of minorities and potential differences related to gender in risk assessment (both in research and practice)	Rise visibility of the problem (collection of more disaggregated data)	Lack of credibility, development of imposter syndrome
Lack of education, communication and outreach and engagement	The higher vulnerability of women and children in certain socio-cultural environments	Gender mainstreaming with leadership and inclusion in disaster management policies and practices	Sexualization and harassment (leading to exclusion or not)
Lack of adaptation, weak resilience	Gap between theory and practice	Rise awareness on the issue, support education and empower women	Lack of respect due to stereotypes and regardless of role
Lack of high quality data and data accessibility. Data dispersion. Lack of citizen science data implementation	Gender is not a problem	Inclusion of gendered specific response and recovery measures	Mined life-work (actual or potential) enhancing the glass-ceiling or not
Lack of proper risk assessment and long term forecasting for climate change, weather extremes and anthropogenic impact on the environment	Cultural systemic inequalities	Promote mentorship and female role models. Engage more with female students	Issues related to culture, geography, age, language and ethnicity
Lack of forecast technologies and lack of early warning systems	Lack of female representation in leading positions and diffuse male dominance	Provide equal support and recognition. Change the reward structure, improve selection transparency and close the pay gap	Gender pay-gap, position discrimination
Progression of vulnerability: overpopulation and exploitation of natural resources. Inequalities and forced migration		Hire more women especially in leading positions. Apply quotas rule and control its actual application	Exclusion of female necessities and from performing tasks in fieldwork and laboratory
Lack of multidisciplinary research and solutions. Lack of sustainable measures related to specific conditions (cultural, social, geographical, economic)		Provide a safe environment where women are really heard, believed and supported	Experienced outside academia only
		Promote a life-work balance	
		Create a culture of change beyond gender stereotypes	

98

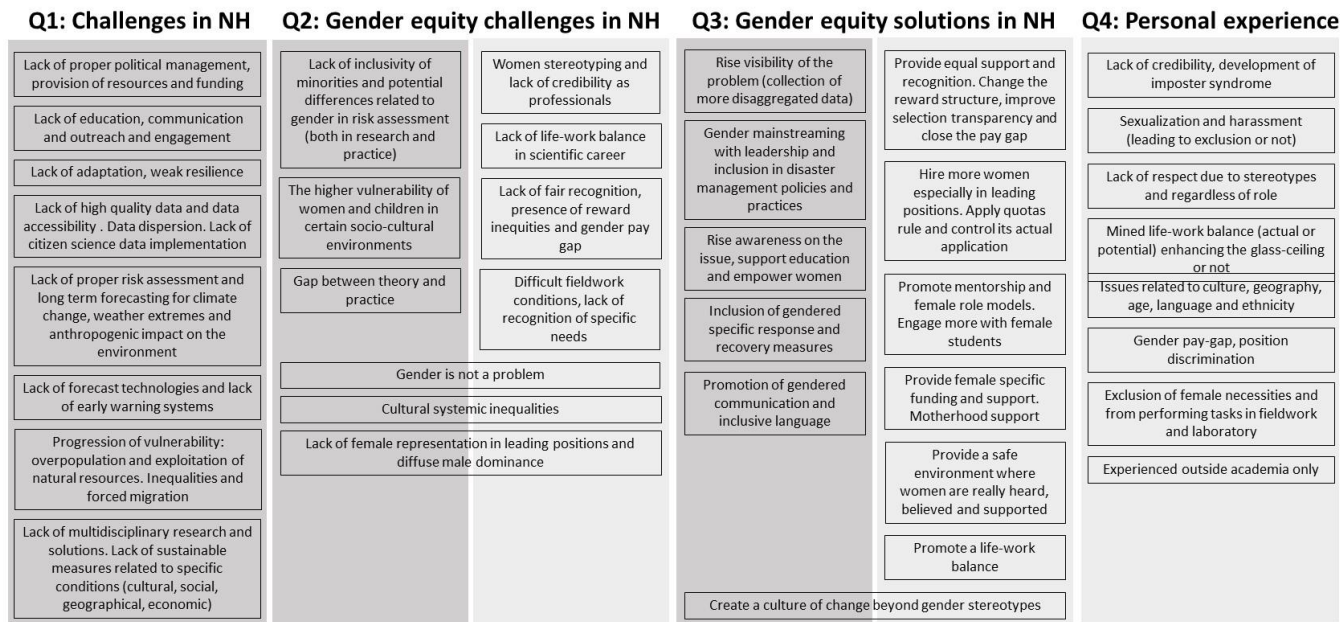

99 ~~Figure 1: Summary of the categories of challenges and solutions in natural hazards (NH) related to gender equity and~~  
100 ~~personal experiences. In dark grey, natural hazards related responses, while in light grey, professional and career~~  
101 ~~development related responses.~~

## 102 2.1 Natural hazards biggest challenges

103 Natural hazards and disaster reconnaissance have been widely investigated among professional, government, and  
104 academic experts. Somewhat lesser is the state of the arts regarding the natural hazards community's grand challenges  
105 to direct new approaches for investigation. For this reason, we asked ~~women our respondents~~ to express the most  
106 critical challenge in natural hazards research (Q1) with no limiting context. ~~The importance to start from global to~~  
107 ~~local (from natural hazards in general to gender equity and personal experience) aimed at help the interviewee to get~~  
108 ~~into the topic and too of starting from global to local (from natural hazards in general to gender equity and personal~~  
109 ~~experience) aimed at helping the interviewee to get into the topic and value theirits own professional knowledge and~~  
110 ~~experientise about natural hazards. In addition, we wanted to check, despite the question being explorative in nature,~~  
111 ~~whether women would have connected the biggest challenges of natural hazards to broad concepts of vulnerability,~~  
112 ~~fragile communities, vulnerable groups despite the question being explorative, we wanted to check whether women~~  
113 ~~would have connected the biggest challenges of natural hazards to broad concepts of vulnerability, fragile~~  
114 ~~communities, vulnerable groups, and similar. This because it has been always the greatest stereotype associated to is~~  
115 ~~because it has always been one of the greatest stereotypes associated with women (i.e., the most dedicated to caring~~  
116 ~~activities and fragile and fragile part of the couple). Instead, (The most perceived challenge (44.3%) is relateds~~  
117 ~~to climate change and extreme events, focusing on the difficulties of long-term forecasting and predictive models due to~~  
118 ~~the interchange of anthropogenic impacts on the environment.~~

119 ~~Similarly, amwise,~~ in Frontiers, Wartman et al. (2020) found that computational simulation and forecasting are  
120 essential tools for decision making and planning, but they still represent a challenge to the professional community.  
121 ~~This result evidences that women professional in natural hazards do not differ from their counterparts, and any of their~~  
122 ~~possible more prominent caring attitudes and sensitivities can affect their perceptions overs in natural hazards do not~~  
123 ~~differ from their counterparts. None of their possible more prominent caring attitudes and sensitivities can affect their~~  
124 ~~perceptions of their work priorities and directions. To continue, respondents, belivedbelieved that One-one of the most~~  
125 evident constraints is the high complexity and data requirements for model development to provide a reliable forecast  
126 concerning the short observation periods, which increases uncertainty. As evidenced by the 10% of the sample,  
127 problems with data are multifaceted, and data quality, accessibility, and transparency are an utmost priority. This is  
128 especially true when "research solutions are [...] translated into operational procedures [...] without considering the  
129 actual legal framework or the availability of data, referring to a resolution [being too small or too large] that in  
130 practice is not used by the managing authorities" ID84. This mismatch can generate "[...] confusion among  
131 practitioners and managing authorities" with difficulties harmonising the results and consequent miscommunication  
132 risks. Uncertainty is considered a prominent issue in this regard, especially concerning the unpredictability of climate  
133 change as widely acknowledged among scientists. These are challenging communication efforts, especially when  
134 communities lack trust in authorities' decisions or due to competitive objectives and interests.

Formatted: Width: 27,94 cm, Height: 21,59 cm

135

136 Figure 1: Summary of the categories of challenges and solutions in natural hazards (NH) related to gender equity and personal experiences. In dark grey, natural

137 hazards related responses, while in light grey, professional and career development related responses.

138  
139 Enhancing communication is on the top priorities for 1744 interviewees (13.936%), highlighting that “our biggest  
140 challenge as scientists is to convince the general public and politicians about our scientific findings and to be able to  
141 communicate them properly, in a language that they can understand” ID30. Problems with comprehension may also  
142 derive from a “lack of consensus concerning basic definitions (hazard, risk, vulnerability, resilience), leading to  
143 misunderstandings or misuse of these terms” ID52 that ~~are able to can~~ affect authorities who can neglect the  
144 information received. 27% of interviewees also pointed to a lack of proper political management and insufficient  
145 resources and funding. In this regard, it is even more prominent the need for a “[...] stronger dialogue between  
146 scientists and governments, [for the] identification of strategies and solutions that might be effectively implemented  
147 in the real world, thus promoting a research that might really contribute to the solution of real-life problems and not  
148 remain in the academic discourses” ID60.

149 Integrating multidisciplinary perspectives into this dialogue would significantly enhance the approach  
150 (methodological and communicational) towards such a complex field of research, ~~believed by 27.9% of~~  
151 ~~respondents~~ which 27.9% of respondents believed. Respondents also indicated a lack of multidisciplinary, with a  
152 concurrent lack of transversal competencies and integrated solutions for multidimensional problems. Integrating  
153 multidisciplinary perspectives into this field would significantly enhance the approach towards such complex  
154 phenomena. Multidisciplinary in natural hazards means “[...] build and use land planning integrated multi-risks  
155 models which are able to contain both multi-hazard analyses (including hazards evolutions due to climate change)  
156 and complex exposure elements (including population migration, natech components)” ID33, that “deal with the  
157 underlying conditions that influence (social and physical) vulnerability to natural hazards, namely, poverty and  
158 inequality” ID37. This may be well explained by Diekman et al. (2015) that analysed women’s motivation for  
159 undertaking a STEM career (for study or work). Collaborative goals, such as translating theory into practice to help  
160 communities advance and enhance development, traditionally appear to lack in the STEM fields. Inter- and  
161 transdisciplinary research may therefore be a women’s professional requirement to be able to consider the multifaceted  
162 nature of the problem. However, although it is widely recognised, it is still very much concentrated within specific  
163 disciplinary areas (Latour, 2004). Datta (2018) also recognised the need to overcome dynamic notions of static  
164 disciplinary practice welcoming interdisciplinary research training to solve and understand the practical challenges  
165 from various perspectives. In this regard, we need to “[...] step outside western norms” ID27, and the influence that  
166 cultural and social relations and power may have on our approach to research: “[...] I think that in natural hazards  
167 and Earth sciences, in general, we are suffering from a crisis of (lack of) diversity. I think there are many reasons for  
168 this. Some are historical, and we can hope that they begin to change as the conversation around diversity becomes  
169 more open [than it is now], but some are cultural. Academia does not always foster an environment where these open  
170 discussions can be had, and where people are held accountable for their actions ” ID98; thus, a strong connection  
171 with collective and policy responsibility exists. Datta (2018) referred to indigenous knowledge. However, we believe  
172 we can expand the discourse to collaborative research knowledge that is culturally appropriate, respectful, honouring,

173 and careful of the local community promoting anti-racist, gender-inclusive theory and practice, cross-cultural research  
174 methodology, critical perspectives on environmental justice, and land-based education.

175 The call for a more inclusive and ethical science that is useful, usable, and used (Aitsi-Anselmi et al., 2018) is  
176 prominent among the respondents and ascribable to the progression of vulnerability investigated and underlined in the  
177 last decade of research in natural hazards and disaster management. Vulnerability but also the progression of  
178 vulnerability for multiple interactive factors is challenging for 16.4% of respondents. A response recognised such  
179 “[...] underlying conditions that influence the social and physical vulnerability of natural hazards, [are] poverty and  
180 inequality” ID37. The representation of women in disaster risk management, who are mostly “[...] invisible and are  
181 not heard” ID95, but also “women in science and leading positions are still a minority, and therefore their  
182 performance and opinions are also sometimes underestimated” ID41 (see chapter 2.2 and 2.3). Two respondents  
183 believe that the increased impacts of global warming and the concurrent increase in weather extremes can have an  
184 impact on the most vulnerable individuals globally, “[...] seeing more [environmental] migration” ID79 and “[...]”  
185 lead[ing] to [a] reorganisation of populations” ID80. However, despite the financial investments towards natural  
186 hazards mitigation infrastructures, there is much consensus that they are still not evenly distributed, “even within  
187 wealthy nations” ID79. Adaptation, resilience, and sustainable solutions are challenging for the 18% of respondents,  
188 who reported **greasignificant**er obstacles in creating a culture of risk (by increasing awareness) because some natural  
189 hazards cannot be prevented, as they are natural geomorphic processes. Is “[...] the human behaviour in responding  
190 to a natural disaster [that] can make the difference” ID86. Not only, a respondent stated that it is a challenge to  
191 “address inequities for people in [the] location of hazards, access to mitigation/adaptation/preparation/recovery  
192 resources, access to hazard warnings, research/observing near underserved communities” ID103; but also “rather  
193 than the technological progress the biggest challenge is reducing the losses where resources are not available” ID93.  
194 The last 13.1% argue instead about the poor forecast of hazards, poor understanding of the complexity of phenomena  
195 occurrence and their effects, and lack of early warning systems.

## 196 2.2 Natural hazards and gender equity: challenges and solutions

197 Natural hazards affect individuals without fixed distinctions of their gender, and it is important to not over-generalise  
198 a popular trend that sees women vulnerable per default. However, case-specific disaster losses demonstrate how  
199 women and girls are more likely to be disproportionately affected by disasters during and in the aftermath of disasters,  
200 a situation exacerbated by the increase of climate change-induced hazardous events (Neumayer and Plumper, 2007;  
201 Fatouros and Capetola, 2021). The impact includes unprecedented challenges regarding health and well-being, for  
202 example, high rates of mortality and morbidity, prolonged psychological distress, and exposure to high-risk domestic  
203 environments (Fatouros and Capetola, 2021; Thurston et al., 2021)<sup>1</sup>, also hampering their opportunity to gainful  
204 employment after the occurrence of a disaster. Socio-economic conditions and cultural beliefs, social norms, and

<sup>1</sup> Disclaimer: the topic of wellbeing, gender and natural hazards related to psychological and physical burdens (e.g., violence or suicide in the aftermath of a disastrous event) has not been included in the current manuscript because of the lacking competencies to develop such complex clinical topic. In addition, noneany of the respondents considered this topic in their answers.

Formatted: English (United Kingdom)

Formatted: English (United Kingdom)

Formatted: English (United Kingdom)

Formatted: English (United States)

205 traditional practices contribute to the complex progression of the vulnerability of women in the wake of natural hazards  
206 and disasters, recognised by 12.3% of respondents. Cultural, systemic inequalities emerge especially in “[...] *lesser-*  
207 *developed countries, but almost everywhere [where] women are paid less and thus have less to respond to disasters*”  
208 *ID45*. In addition, it is more difficult for a female-headed household to acquire financial assistance and loans that are  
209 essential in the post-disaster rebuilding and re-establishing processes (Alagan and Seela, 2011; [Fatouros and Capetola](#)  
210 [2021](#)).

211 Systemic inequalities are also perceived at the family level, because as a respondent expressed, “*women are less*  
212 *encouraged to take information on their own, in most cases, they listen to their partner and agree with their decisions*”  
213 *ID82*, which is not new in literature (Cvetkovic et al., 2018). Patriarchal families can experience communication  
214 problems within the domestic sphere and in the wake of natural hazard occurrences ([Cvetkovic et al., 2018](#); [Thurston](#)  
215 [et al., 2021](#)). In this context, a respondent added, “[...] *the most obvious challenge is the need to find ways to give*  
216 *women a voice in some countries where, again, the society is male-dominated. Women will often be the people in the*  
217 *household responsible for preparedness and planning activities related to natural hazards. Yet, their opinion may not*  
218 *be sought when decision and policymakers put together plans for improving household resilience*” *ID109*. Another  
219 respondent, in fact, imperatively stated, “*educat[e] women to react and survive. The experience of the Indian Ocean*  
220 *tsunami 2004 is that women died more than men because they waited at home for their husbands to leave their homes*”  
221 *ID91*. In practical terms, 18.9% of the respondents asked for more awareness and support for educational and  
222 empowerment activities for women. “*Women have unfortunately globally [fewer] opportunities for education and*  
223 *might therefore already be running behind in their understanding of natural hazards and how to prepare themselves*  
224 *and their communities. More effort should be done to reach female communities and educate them*” *ID104*, expressed  
225 a respondent sharing the concerns of many others who additionally argue for “[...] *enhanc[ing] the connection of*  
226 *women in the field of natural hazards and make their voice heard*” *ID19*.

227 The concept of unheard voices is well experienced personally by most respondents and is found in chapter 2.3.  
228 Awareness should not be considered just a means but also a place. We found an interesting comment of a respondent  
229 asking for “[...] *the creation of safe spaces to consider fully the impacts on women in the event of hazard events, and*  
230 *their experiences and frustrations as researchers*” *ID27*. This approach recognised the need for a horizontal space of  
231 dialogue in DRR, where no top-down or bottom-up approaches are considered. Women’s accumulated skills,  
232 experiences, and capabilities in times of natural catastrophes are often not adequately identified, recognised, and  
233 promoted. Women’s participation in DRR decision-making processes at all levels throughout the world is meagre. In  
234 this respect, 18% of respondents perceive a lack of inclusivity (of minorities in general, thus extending the vulnerable  
235 pool) and potential differences related to gender in risk assessment (both research and practice). Inclusivity has been  
236 advocated to be “[...] *not just to reach a quota and not only if they first have to be more like the majority (e.g., men-*  
237 *like women, rich coloured people)*” *ID36*. Respondents share the concern that women and other gender minorities do  
238 not have a seat at the table when it comes to disaster risk management and resilience. Hence, their needs and interests  
239 are excluded from disaster management programmes (Dominey-Howes et al., 2014; Gaillard et al., 2018; Gorman-  
240 Murray et al., 2018), which fail to recognise their diverse economic, political, legal, occupational, familial, ideological,

241 and cultural backgrounds (Zaidi and Fordham, 2021), creating many issues during response and recovery stages  
242 (Hemachandrea et al., 2017; [Thurston et al., 2021](#)). However, women are considered agents of change with unique  
243 skills, qualities, and expertise benefitting quality governance (Gurmai, 2013) through accuracy and transparency in  
244 the decision-making process (Araujo and Tejedo-Romero, 2016). Gender inclusion in DRR is recognising and  
245 welcoming differences rather than accepting homogeneous thinking. Respondents' testimonies make us realise that  
246 the personal experiences in DRR research and management are well integrated into individuals' cognitive and  
247 experiential [backgrounds](#). 31% of respondents argue for gender mainstreaming with leadership and inclusion in  
248 disaster management policies and practices. They recognise female underrepresentation in leading positions and male  
249 dominance in decision-making bodies and communities related to the disaster cycle (18.9%). A respondent is  
250 convinced that *"[...] better equity between genders in governing bodies would modify the decision trees of the  
251 authorities, particularly in terms of mitigation and long-term view pattern[s]" ID33.*

252 [6.6% of respondents to question Q2 believe that gender is not a \(big\) problem in natural hazards. Most of their  
253 statements/responses refer to positive personal experience in their professional career and the opinion that \*"\[...\] science  
254 is likely one of the field\[s\] that suffers least of gender un-equality. At least in the western countries. \[...\]" ID86.\*  
255 \[Interestingly, none of these nineeight respondents considered gender an important variable in the disaster assessment  
256 or its vulnerability construction. We discuss more about positive changes experienced by the respondents in terms of  
257 gender equity in the professional sphere in chapter 2.3.\]\(#\)](#)

Formatted: Font: Not Italic

258 All the above demonstrates a literature gap in identifying the ways to improve the role of women in disaster risk  
259 governance derived by a gender data gap that still exists. 7% of the respondents found it a priority to collect more  
260 disaggregated data to raise the visibility of the problem when assessing risks and adaptation options of natural hazards,  
261 recognising gender differences without mainstreaming the stereotypes. That might give the idea of gender to be merely  
262 connected to a vulnerable condition (Roder et al., 2017) and to be exclusively related to women, promoting  
263 stereotypical notions of women as "victims" or the "weaker sex" (Zaidi and Fordham, 2021). This is because, often,  
264 vulnerability assessments do not emphasise the fact that individuals simultaneously belong to multiple and  
265 intersectional social groups - gender being just one of these - from which they draw their identities and which shape  
266 their risk profile in the context of disasters (Zaidi and Fordham, 2021). Real progress towards gender mainstreaming  
267 into DRR needs a cultural change beyond gender stereotypes (13% of responses). Possibly, *"[...] it would be great if  
268 there could be some overarching guiding principles that all institutions could adhere to, but academia is quite  
269 fragmented, so I think it really comes down to individual institutions fostering open conversations and using these to  
270 drive change" ID86.* Education is still considered at the base of the change, able *"to build bridges [and] not barriers  
271 between each other and to see the richness in diversity and inclusivity" ID112.*

272 Finally, the need to include gender-specific response and recovery measures is an utmost priority for 4.1% of  
273 respondents, where 0.8% argue for a gendered and inclusive language and communication. So, by combining multiple  
274 concepts [aroused/brought up](#) by the interviewees: we need women, and we need to use appropriate language when  
275 including them in the DRR policy and practice. However, which women should be involved? This is the interesting

276 question that Enarson (2009) expressed in one of the latest books. She recognised the need to consult and involve local  
277 women's organisations and networks, including development and grassroots organisations active in high-risk areas.

278 We can conclude shortly that there is no 'silver bullet' to solve gender equity in natural hazards. However, there is a  
279 need to know how useful and effective concrete examples, specific suggestions, action guides, and indicators are to  
280 mainstream gender into DRR.

### 281 **2.3 Professional development and gender equity**

282 The questions related to natural hazards and gender equity (Q2 and Q3) had been received to be related to natural  
283 hazards per se (see chapter 2.2) and for some others to professional development (Figure 1, light grey boxes). Only  
284 Q4 specifically addressed gender-based issues in the work environment; in particular, we asked for personal  
285 experiences. Since personal experiences and general challenges often coincide, we have used both to address the  
286 abundant issues still residing within the community and the actions to be implemented for a more inclusive work  
287 environment. The challenges perceived in natural hazards related and gender equity (Q2) are for the 37.7% of  
288 responses related to the lack of role models and female representation in decision roles and leadership positions,  
289 showing the range of career possibilities and paths. In addition, 36.1% of respondents (Q2) evidenced unresolved  
290 challenges related to an unfair reward structure, pay gap, life-work imbalance, stereotyping and lack of recognition  
291 in a male-dominated field. However, these are not just perceptions, but they are matched by 73.8% of personal  
292 experiences (Q4), who have confronted career advancement and unfair treatment obstacles.

293 In detail, 27.9% experienced being attributed a lower salary compared to male colleagues and being discriminated  
294 against obtaining leadership positions: "[...] More visibility is given to male colleagues all the time. Even more power  
295 and resources are given to them. In my place of work (State organisation), power positions belong 100% to men, [...]"  
296 ID17. Moreover, 14.8% of respondents also experienced or witnessed life-work imbalance particularly worsened due  
297 to unequal expectations of women and men's family responsibilities. A respondent reported that "it has always been  
298 very difficult to combine motherhood with the challenges of making a career [...]" ID37 and another echoed that "it  
299 has been very hard to find role models in my field when I took the decision of having a family. I had no reference for  
300 a successful woman in my field with children [...]" ID69.

301 Unfair treatment has also been experienced widely by our respondents. A respondent reported, "My opinions have  
302 been quite often undervalued by other colleagues. Even when I was the PI of a project, some people preferred to speak  
303 to male colleagues" ID110. Compared to male colleagues, a lack of credibility was reported by 27.9%, a lack of  
304 respect regardless of role by 23.8%. Sexualisation and harassment were reported by 13.9%. One of the interviewees,  
305 unfortunately, shared one of the most negative experiences: "[...] Anything deemed "feminine" about me was used  
306 against me as a weakness. Constant inappropriate talk [was] designed to see if it would get a reaction out of me by  
307 my co[-]workers. In the field, free time was spent at the bar or even hostess lounges, and I was incredibly  
308 uncomfortable [...]. Then I was put in a closed-door meeting with just my supervisor and asked how working there as  
309 a woman was. I felt very unsafe and therefore unable to be truthful [...]" ID79. Discrimination can be so pervasive to

310 induce repression of one's traits, to the point of feeling "[...] pushed to be more "masculine" in the workplace to fit  
311 in" ID79. To our dismay, the biases and stereotypes reported, and the harassment experienced are not new to women  
312 working in male-dominated disciplines or literature (Kenney et al., 2012), news outlets and documentaries (Picture a  
313 Scientists, 2020). Despite the wide recognition of the problem, progress is still slow. Cultural, systemic inequities are  
314 part of this problem and are linked not only to gender stereotypes but also to age, ethnicity, religion and nationality  
315 (9.8% of respondents).

316 Finally, 8.2% of respondents reported issues related to fieldwork: they experienced exclusion and lack of consideration  
317 of their specific needs precluding them from performing tasks. In some cases, the problem is again very much related  
318 to performing capabilities stereotypes; one respondent reported, "[...] Many times in the field I was asked, "are you  
319 sure you can do this (going uphill, going down, dirt myself)? [...]" ID44. But also feeling uneasy "[...] about certain  
320 accommodations (e.g., bathroom) that I feel I might be imposing on my peers, and thinking twice about taking valuable  
321 measurements in areas where my safety might be at risk" ID101.

322 A positive trend has been observed concerning structural changes in recent times. For example, one respondent who  
323 experienced discrimination in the past recognised that "[...] female colleagues entering the field now, with solid  
324 competencies and a lot of "guts", have much more chances now to move up to decision positions [...]" ID23. In  
325 addition, 23% of respondents explicitly said they did not experience any gender-related career challenges reporting  
326 their positive experience in a supportive environment and gender-mixed teams (both at the educational and the  
327 professional level). Although for a couple of respondents, the personal experience was positive, they reported being  
328 aware of gender-related challenges encountered by other female colleagues.

329 We can conclude that the struggle for women to find inclusive work environments was and still is not resolved, despite  
330 recognising positive efforts in the right direction and some virtuous examples. Solutions concerned with promoting  
331 gender equity in the work environment are envisioned by 54.1% of the responses [to Q3](#). The proposed solutions will  
332 not read unfamiliar to those accustomed to the debate in the broader gender-related STEM career challenges:  
333 "Diversity begins at the top. Work to understand why retention is challenging and change reward structures. Put  
334 women in leadership positions. Refuse to hold all-male panels, all-male sessions, all-male anything" ID42, said one  
335 respondent, well summarising the general feeling of the interviewees.

336 43.9% of responses suggested enhancing selection transparency via providing equal support and access to resources  
337 and information, recognising women's work, and changing the reward structure, ensuring an experience-based salary  
338 to close the gender gap. Bell and co-authors advocated for such changes and actions almost 20 years ago (Bell et al.,  
339 2003). It is noteworthy and disappointing how slow the process to equity is if we still discuss the benefit these changes  
340 would accomplish today. Indeed, many institutions have taken steps forward in these regards. However, the mission  
341 is far from being complete, and possibly one reason is that the efficacy of actions undertaken is often not measured or  
342 not publicly shared (Timmers et al., 2010; McKinnon, 2020). Promoting women's work reflected 31.8% of responses  
343 calling for hiring more women, particularly in high profiles and relevant positions, as a solution. To achieve that,  
344 quotas are one of the actions commonly proposed. Quotas have been since long introduced in many institutes and

345 funding organisations and resulted in an effective reduction of the gender gap in leading roles in certain areas (Handley  
346 et al., 2020; Pellegrino et al., 2020). However, as also some respondents noted, quotas rules may appear only on paper  
347 at times. They may also be seen as controversial or counterproductive, reinforcing old stereotypes (Handley et al.,  
348 2020, Pellegrino et al., 2020). We believe that quotas can be a double-edged sword able to raise negative opinions  
349 among women in the workplace, undermining their credibility. However, until more transparency is enacted, quotas  
350 can be a valuable instrument to promote and normalize more gender-balance environmentsquotas can be a valuable  
351 instrument to promote and normalise more gender balance environments until more transparency in selection  
352 procedures is enacted.

353 One respondent, for example, pointed out, “[...] as a woman, I am always extremely disappointed when positions are  
354 open only for my gender. First, because it means that male[s] in this specific institution had the power to only employ  
355 other males. Second, because women employed at such positions can always be taught that they only got it because  
356 of their gender, not their capacities” ID12. A global survey targeting Earth and Space scientists by Popp et al. (2019)  
357 clearly showed the divided opinion on quotas. They noted how quotas’ favour tends to be gendered, with 44.9% of  
358 women and 27.9% of men sharing a favourable opinion and career stage related. Among women favouring quotas,  
359 56.1% are postdocs, while among men the 34% hold a professor position. They concluded this result showed a clear  
360 sign of a disadvantage for early-mid career women and a fear of being negatively affected by quotas for mid-career  
361 men geoscientists (Popp et al., 2019). Handley et al. (2020) have analysed the gender balance in universities in  
362 Australasia and noted that even if quotas regulations were in place, few-to-no women would apply to vacancies for  
363 various reasons. Therefore, to counteract the issue, they proposed creating a database of female professionals working  
364 in geosciences divided by area of research. Such a database can be used to find new collaborators, advertise vacancies,  
365 and invite applications from relevant candidates (possibly leading to a larger number of female applicants), inquire  
366 about consultancy, ask for an interview, and pool for surveys. We find this solution interesting and responding to the  
367 needs of giving equal career opportunities while maintaining a transparent process and recognising female  
368 professionals. Such a database could also be used to promote female-specific mentorship and role models, including  
369 increasing the visibility of women’s work and thus help engage more female students and potentially retain them in  
370 the field, as noted by 27.8% of responses. On mentoring and role models, Handley et al. (2020) highlighted an  
371 important point. Since not many women occupy apical positions yet, horizontal mentoring among women peers or  
372 close in the career stage can also be a good option. For several years, several associations have made their primary  
373 goal providing support and mentoring to women in geosciences. To cite a few at the international level, the 500 women  
374 scientists established in 2016, the Earth Science Women’s Network (ESWN, Adams et al., 2016) and Geolatinas  
375 founded in 2002. A complete list of women-focused and women-led geoscience and related networks are available in  
376 Handley et al. (2020). Moreover, female-specific funding and support schemes, including those specific for supporting  
377 motherhood, are solutions for 21.2% of respondents. The latter goes together with the promotion of life-work balance,  
378 the acceptance of part-time careers and a better redistribution of roles and responsibilities, which are seen as significant  
379 help by 13.6% of responses. In addition to promoting more women in our work environments and provide adequate  
380 support, institutions must become safe places where people in “[...] positions of power and administration take

381 *harassment claims seriously and stand by a zero-tolerance policy and made women feel comfortable and believed*  
382 *when reporting these issues” ID80, said a respondent, reflecting the 15.2% of responses.*

383 We can conclude that one of the main steps forward with the potential of a profound impact resides in a broad cultural  
384 change that will break down those still longing stereotypes and allow real diversity inclusion. 27.8% of responses  
385 explicitly hope for this change in the work environment, but it is possible to include all actions proposed in this much  
386 broader resolution. Cultural changes are slow to achieve. Keeping up a constructive debate and the attention around  
387 the topic helps as much as the proposed change in the reward structure, the promotion of women’s work, hiring more  
388 competent women for apical positions, ~~and~~ providing motherhood-specific support and ~~redefine-redefining~~ roles and  
389 responsibilities. ~~We do not exclude the immense necessity towards the normalisation of co-parenting and genderless~~  
390 ~~or gender equivalent parental initiatives. We believe that there are very prominent actions undertaken into this~~  
391 ~~direction in some countries. However, they are political regulations where we, singularly, have few little to no control~~  
392 ~~of. Instead, institutions (or companies) can lead the change and become the first promoters of equal provide support~~  
393 ~~tesupport with well-thought plans and effectiveness assessment-those parents, unluckily most of the time being the~~  
394 ~~female counterpart, when needed.~~

395 One more way to foster profound changes passes by promoting ~~the use of~~ inclusive language at all levels, particularly  
396 from people in leadership positions, regardless of their gender. Language shapes profoundly our mind, our way of  
397 interpreting the world we live in, the words we use can discriminate as much as they can empower (McKay et al.,  
398 2015; Taheri, 2020). Where not yet in place, specific training on inclusive language and unconscious bias should be  
399 organised at institutions and organisations and possibly be made mandatory with a top-down priority.

400 The solutions envisioned by the pool of respondents to our survey are very similar to strategies already highlighted in  
401 the literature, reported in Table 2. We can conclude that strategies, actions, and solutions are well defined and, in some  
402 instances, already enacted. However, monitoring the efficacy of these actions is far more complex but of great  
403 relevance to understanding which of them is worth pursuing and which instead do not provide significant improvement  
404 towards closing gender-based issues. Timmers et al. (2010), analysing aggregated data for employment in the year  
405 2000-2007 in 14 universities in the Netherlands, could observe that the larger the number of gender equality policy  
406 actions adopted, the more significant the reduction of the glass ceiling. However, they criticised the lack of internal  
407 evaluation of the adopted measures by the universities themselves. Universities, research institutes and organisations  
408 should promote researching and applying adequate methods for monitoring their strategies and implementing them  
409 with high priority.

410 *Table 2. Summary of strategies and envisioned solutions towards gender equity in STEM and geoscience from recent*  
411 *literature and this study. It can be observed how the proposed solutions align well among themselves showing strong*  
412 *similarity, when a solution has been proposed that does not find direct comparison the related box is left blank.*  
413 *\*Handley et al. (2020) focus mainly on the Australasia situation. However, these data are fundamental to be also*  
414 *gained elsewhere in the world.*

Vila-Concejo et al. (2018)	Popp et al. (2019)	Handley et al. (2020)	This perspective
Redefine success	Transparent candidate selection criteria of institutions and funders for hiring processes and funding opportunities	Re-think excellence recognition and reward criteria	Provide equal support and recognition. Change the reward structure, improve selection transparency, and close the pay gap
Advocate for more women in prestigious roles	Better promotion and representation of female scientists by selecting them for prestigious decision-making roles in scientific organisations and institutions	Raise the visibility of women through open-access databases	Hire more women especially in leading positions. Apply quotas rule and control its actual application
Encourage more women to enter the discipline at a young age		Greater promotion of the value of mentoring and provision of inclusive mentoring programs	Promote mentorship and female role models. Engage more with female students
Create awareness of gender bias	Mandatory gender bias training to combat unconscious biases	Engage all the geoscience community to create sustainable change	Create a culture of change beyond gender stereotypes
Get better support for the return to work	Granting more rights, flexibility, and support for parents to share parental responsibilities and to transform academia into a more family-friendly workplace		Promote a life-work balance
Promote high-achieving female			Provide female specific funding and support. Motherhood support
Speak up		Eliminate and actively address everyday sexism and harassment in geosciences: Field trip code of conducts	Provide a safe environment where women are really heard, believed, and supported
		Gather more data on why women leave geosciences*	
	Inviting more men to an open discussion about gender equality		

Formatted: Font: 9 pt

### 416 3 Getting down to business

417 From the responses analysis and state of the art literature, we have understood that gender-based challenges at the  
418 professional level and within the disaster cycle are very close. Moreover, because of their interrelation, the solutions  
419 proposed may not be exclusive for a professional or a more technical sphere, but they can work simultaneously, with  
420 mutual benefit. Early education is key to fostering a cultural revolution. If children attend classes related to social  
421 norms, diversity, and inclusion, they might become adults able to go beyond individuals' gender. If so, women and  
422 other gender minorities would be much more considered at the leading positions in DRR institutions or academia, thus  
423 promoting a more comprehensive vision about vulnerabilities before, during, and after natural hazards occurrence.  
424 But the cultural change must also be vertical in a top-down approach by organising specific compulsory training for  
425 leaders and professionals to explain biases and stereotypes and fight them to promote a more effective and just natural  
426 hazards management and, thus, a more inclusive society. In addition, the scale of the change should consider the  
427 horizontal space in which role models are found within peer networks to promote and support positive imitative  
428 behaviour.

429 For what concerns the guiding principles and institutions, several examples highlighted in this perspective showed  
430 how the political agenda (e.g., SFDRR) lacks any gender-related practical guidance. So do all other local  
431 administrations and institutions. Many gender-inclusive initiatives are short-term and aim primarily to spark interest  
432 rather than build skills. ~~with, m.~~ Most of the time, ~~they are being~~ just a box 'ticked' rather than an effective action.  
433 Therefore, we advocate for compulsory study, implementation, and application of methods to measure and monitor  
434 over time the efficacy of actions and strategies put in place at institutional, national and international levels.

435 In addition, current gender-inclusive initiatives are excluding men despite literature demonstrating a disjunction  
436 between the assumptions and lack of understanding of the reality of men's lived disaster experiences (e.g., Rushton et  
437 al., 2020). What Fordham and Meyreles (2014) called a paradox, masculinity, which contributes to the structure of  
438 power that privileges men, can also put men at risk (e.g. [Jonkman and Kelman, 2005](#); [Ashley and Ashley, 2008](#);  
439 [Fitzgerald et al., 2010](#)). Similarly, we can observe how in the professional domain, specific jobs and disciplines are  
440 still perceived as belonging to a (stereotyped) female world only and where men are seen as outliers. If the final goal  
441 is a truly inclusive society, we must be aware of all the biases and stereotypes we are surrounded by and counteract  
442 all of them appropriately. The future of research in natural hazards and disaster mitigation and our professional domain  
443 needs to include all voices and find allies in the privileged categories of the specific domain of interest. We think that  
444 lessons learnt within the context of women discrimination can serve as starting point to expand the discourse to other  
445 gender minorities and that intersectional research should be advocated for to gain an all-inclusive approach and  
446 understanding of disaster stories that foreground differences.

### 447 5. Authors' contributions

448 All authors have contributed to the Conceptualization and Data curation. VC and GR have equally contributed to the  
449 analysis and preparation of the first draft. All authors have contributed to the revision and editing of the manuscript.

450 **6. Competing interests**

451 Author HK is executive editor of the journal NHESS.

452 **7. Special issue statement**

453 The manuscript is submitted as part of the Special Issue “Perspectives on challenges and step changes for addressing  
454 natural hazards.”
