
22 significantly. The influence of earthquake on slope stability is significantly greater than
23 that of rainfall. The corresponding safety factor when the vertical seismic action is
24 vertically downward is smaller than that when it is vertically upward. When considering
25 both horizontal and vertical seismic effects, slope stability is lower.

27 Three-dimensional slopes; Rainfall; Earthquake; Stability analysis

28 **1 Introduction**

29 Rainfall-induced landslides are caused by the infiltration of precipitation into the
30 ground surface, leading to an increase in pore water pressure, hence reducing the
31 effective stress and shear strength of the soil. Sustained rainfall or heavy rainfall events
32 can significantly increase the risk of slope instability, especially in those areas with
33 loose, poorly drained soils. Several landslides in the Three Gorges reservoir area have
34 been triggered by rainfall (Yin et al., 2012; Sun et al., 2016b). Earthquakes, as another
35 key factor, impose additional dynamic loads on slopes through ground shaking, which
36 may lead to instability of otherwise stable slopes. In addition, earthquake-induced
37 landslides tend to be more destructive because they often occur without warning. Due
38 to completely different destabilization mechanisms, studies of landslides induced by
39 these two factors are often carried out separately. In some cases, rainfall and
40 earthquakes may act together on slopes. And earthquake-induced landslides may occur
41 more frequently during the rainy season, when the soil is saturated with water and its
42 resistance to earthquakes is reduced. Further research is necessary to investigate the

43 stability of slopes under the combined influence of rainfall and earthquake (David, 2000;
44 Iverson, 2000; Sassa et al., 2010).

45 At present, the main research methods for slope stability include the limit
46 equilibrium method (Bishop, 1955; Morgenstern and Price, 1965; Spencer, 1967), limit
47 analysis (Farzaneh et al., 2008; Michalowski, 1995; Qin and Chian, 2018; Zhou et al.,
48 2017), Finite Element Method (Griffiths and Lane, 1999; Ishii et al., 2012) et al. There
49 have been numerous studies and findings regarding the stability assessment of 3D
50 slopes. However, most of these methods are based on extended 3D equilibrium analysis
51 techniques (Hung, 1987; Zhang, 1988; Chen, 2001; Cheng and Yip, 2007), which
52 rarely strictly adhere to the six equilibrium conditions. Additionally, these approaches
53 often introduce a significant number of assumptions that limit their practical
54 engineering applications. The strict 3D limit equilibrium method proposed by Zheng
55 (2007) is an overall analysis approach based on the natural form of slip surface stress
56 distribution and approximation through shard interpolation. Sun et al. (2016a, 2017)
57 combined Morgenstern-Price and Bell global analysis method to analyze the stability
58 of reservoir bank slope, applying this method to the Three Gorges reservoir area.
59 Rahardjo et al. (2010) studied the effect of groundwater table position, rainfall
60 intensities, and soil properties in affecting slope stability using the numerical analyses.
61 Some of the defects inherent in the two-dimensional(2D) limit equilibrium method
62 remain unresolved, and some of them are even amplified in the complex 3D analysis,
63 which has a certain impact on the accuracy of the 3D slope stability evaluation. For the

64 limit analysis method, it is still difficult to establish the velocity field of the motion
65 permit in 3D space. And numerical methods often suffer from two problems: the
66 determination criteria of the critical state of the slope and the determination of the
67 location of the critical sliding surface. Compared with a single traditional analysis
68 method, the mutual integration of several method theories has also been gradually
69 developed, so as to give full play to the advantages of their respective methods and
70 better used in slope stability analysis, such as the finite element limit analysis method
71 (Ali et al., 2016; Lim et al., 2017; Zhou and Qin, 2022).

72 As a common geological hazard in seismic zones, earthquake-triggered landslides
73 have been extensively investigated by numerous scholars (Sepúlveda et al., 2005;
74 Chang et al., 2012; Jibson and Harp, 2016; Marc et al., 2017; Salinas-Jasso et al., 2019).
75 At present, the stability analysis method of 3D slope is not mature, and the research on
76 the dynamic stability of 3D slope is even more scarce. The quasi-static method (Liu et
77 al., 2001) introduces coefficients (k_v and k_h) that reflect dynamic action, thereby
78 transforming a dynamic problem into a static one for easier resolution. This approach
79 avoids the complexities associated with dynamic analysis and has become widely used
80 in engineering. Horizontal seismic effects are often a significant consideration in slope
81 stability analysis, however, some research (Chopra, 1966; Lew, 1991; Ling et al., 1999;
82 Shukha and Baker, 2008) confirms that the vertical component of seismic forces should
83 also be given great attention. Wang and Xu (2005) employed the dynamic finite element
84 method to investigate the seismic response characteristics of various components in a

85 3D high slope yet failed to determine the safety factor. Guo et al. (2011) obtained the
86 time history curve of slope safety factor during earthquake using vector sum method in
87 2D situations. Cao et al. (2019) studied the seismic response and dynamic failure mode
88 of the slope subjected to earthquake and rainfall by two model tests. **In summary,**
89 **although previous researches have provided significant insights into landslides**
90 **triggered by earthquakes, there remain inadequacies in fully considering the vertical**
91 **effects of seismic activity, extending analysis from 2D to 3D, and comprehensively**
92 **integrating the effects of both earthquakes and rainfall.**

93 Most studies only consider the role of a single factor in seepage or earthquake,
94 neglecting the slope stability analysis under combined working conditions. Therefore,
95 analyzing the change law of safety factors for slopes during seepage and seismic action
96 is of great practical value in guiding slope support design and evaluating slope stability.
97 In this paper, a 3D rigorous slice-free method considering seepage and seismic forces
98 to solve the safety factor of bank slopes is proposed. The proposed method strictly
99 satisfies the force balance and moment balance in three directions, without introducing
100 other redundant assumptions.

101 **2 Rise of phreatic surface and calculation of seepage force with rainfall**

102 **infiltration in the soil column**

103 The phreatic surface is the interface between the saturated and unsaturated zones
104 within the slope. Physical and mechanical parameters of the sliding below the phreatic
105 surface adopt saturated, while above the phreatic surface adopt naturally. A differential

106 soil slice is taken from the slip surface to the slope surface in the landslide body is
 107 shown in Fig. 1. $z(t)$ is the rise of phreatic surface after rainfall infiltration, which
 108 refers to Conte and Troncone (2017), the height of the soil slice below the phreatic line
 109 on BE and CF side are respectively z_1 and z_2 . It is assumed that rainfall is consistent
 110 with groundwater movement and that the slope surface is well drained and free of
 111 standing water. Regardless of rainfall intensity, runoff will form if it is greater than the
 112 infiltration capacity. The height of rise of the phreatic surface within the slope after the
 113 rainfall is

$$114 \quad z(t) = \frac{z_r}{n(1-S_r)} \exp \left[-\frac{k}{ds \cos \alpha} i \cos \delta (t - t_0) \right] \quad (1)$$

115 where z_r is the volume of water (per unit area) that infiltrates the slope due to a
 116 rainfall event with a specified duration, n is porosity, k is permeability coefficient, S_r
 117 is saturation, i is the hydraulic gradient ($i = \sin \beta$), δ is the angle between the slope
 118 surface and the horizontal plane, α is the angle between the sliding surface BC of the
 119 differential soil slice and the horizontal plane, β is the angle between the phreatic line
 120 and the horizontal plane, ds is the length of the sliding surface BC of the differential
 121 soil slice, t is time, and t_0 is the initial moment. As a further simplification, it is
 122 assumed that both n and S_r are constant.

123

124

Fig. 1 Relationship between rainfall and groundwater level

125

126

Fig. 2 Calculation sketch of forces acting on the differential soil slice

Fig. 3 Calculation sketch of hydraulic head

127

128

129 The load on the soil slice is shown in Fig. 2. dW_1 and dW_2 are the gravity of the
 130 differential soil slice above and below the phreatic line. The resultant hydrostatic force
 131 of the boundary AB , CD , and BC are F_1 , F_2 , and F_3 respectively. N is the contact
 132 pressure (effective pressure) between the soil particles, and T is the sliding resistance
 133 force. h_u and h_w are the height of the soil slice above and below the phreatic line
 134 respectively.

135 According to the flow properties of the phreatic line perpendicular to the
 136 equipotential line, the surrounding hydrostatic pressures F_1 , F_2 , and F_3 on the
 137 boundary CF , BE , and BC can be determined. As shown in Fig. 3, BB_1 and CC_1 are
 138 perpendicular to the phreatic line, then make B_1B_2 perpendicular to AB , and C_1C_2
 139 perpendicular to CD . According to the geometric relationship, the hydrostatic pressure
 140 resultant forces at the boundary CF and BE are

141
$$F_1 = \frac{1}{2} \gamma_w z_1^2 \cos^2 \beta, F_2 = \frac{1}{2} \gamma_w z_2^2 \cos^2 \beta \quad (2)$$

142 γ_w is the unit weight of the water. Let $h_w = \frac{1}{2}(z_1 + z_2)$, the hydrostatic pressure
 143 resultant force on the slip surface BC is

$$144 \quad F_3 = \frac{1}{2} \gamma_w (z_1 + z_2) d s \cos^2 \beta = \gamma_w h_w d s \cos^2 \beta \quad (3)$$

145 The components of F_3 in the horizontal and vertical directions are

$$146 \quad U_x = \gamma_w h_w d s \cos^2 \beta \cos \alpha, \quad U_y = \gamma_w h_w d s \cos^2 \beta \sin \alpha \quad (4)$$

147 The gravity of water in differential soil slice is

$$148 \quad dW_{2w} = \gamma_w h_w d s \cos \alpha \quad (5)$$

149 The permeability pressure is a pair of balancing forces with the water weight in a
 150 differential soil slice and the hydrostatic pressure around it (Zheng et al., 2004).

151 Therefore, the weight of water in the differential soil slice and the surrounding
 152 hydrostatic pressure can be replaced by a seepage force. The force diagram in Fig. 2
 153 can be replaced by Fig. 4. dW'_2 represents the effective unit weight of the soil below
 154 the phreatic line and dW_D is the seepage force.

155

156 **Fig. 4** Simplified force diagram on a differential soil slice

157 The horizontal and vertical component of the seepage force dW_3 are

$$158 \quad dW_{Dx} = F_1 - F_2 + U_x = \gamma_w h_w \cos^2 \beta (z_1 - z_2 + dss \sin \alpha) \quad (6)$$

$$159 \quad dW_{Dy} = dW_{2w} - U_y = \gamma_w h_w dsc \cos \alpha \sin^2 \beta \quad (7)$$

160 According to geometric relation

$$161 \quad z_1 - z_2 + dss \sin \alpha = dsc \cos \alpha \tan \beta \quad (8)$$

162 Therefore, the seepage force is

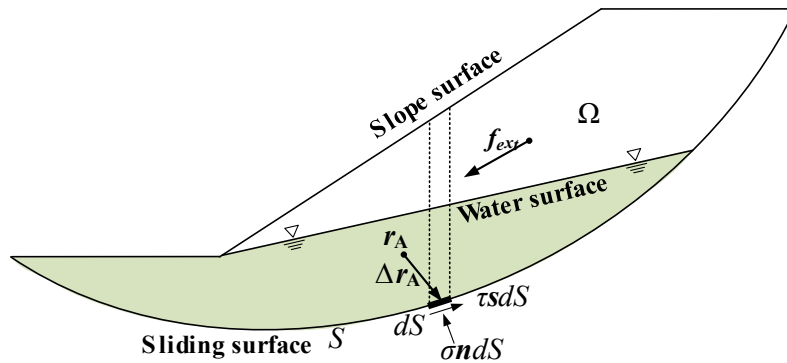

$$163 \quad dW_D = \gamma_w h_w dsc \cos \alpha \sin \beta \quad (9)$$

164 The direction of seepage force is consistent with groundwater flow. The direction
 165 of groundwater flow within the sliding soil mass is determined by the inclination of the
 166 phreatic surface in each differential soil slice. As shown in Fig. 4, the flow direction of
 167 groundwater is oriented at an angle β relative to the horizontal plane.

168 3 A global analysis method for slope stability under seepage and 169 earthquake

170 3.1 Overall system of equilibrium equations

171 As shown in Fig. 5, taking the whole sliding body Ω as the research object, and
 172 S is a potential slip surface.

173

174 **Fig. 5** A 2D schematic plot for force system in/on the sliding body

175 dS is a differential element on the sliding surface S . The normal force on a
 176 differential element dS at point \mathbf{r} is $\sigma n dS$, the resultant shear force is $\tau s dS$, \mathbf{n} is
 177 the unit normal vector at position vector \mathbf{r} on S and pointing to the inside of the sliding
 178 body Ω ; \mathbf{s} is the unit tangent vector at position vector \mathbf{r} on S and opposed to the
 179 sliding direction of the sliding body Ω , so the reaction on dS is:

$$180 \quad d\mathbf{f} = (\sigma \mathbf{n} + \tau \mathbf{s}) dS \quad (10)$$

$$181 \quad d\mathbf{m}_A = \Delta \mathbf{r}_A \times d\mathbf{f} \quad (11)$$

182 Here, $\Delta \mathbf{r}_A = \mathbf{r} - \mathbf{r}_A$, \mathbf{r} is the position vector of dS , \mathbf{r}_A is the position vector for any
 183 given reference point A , “ \times ” represents vector multiplication.

184 \mathbf{f}_{ext} is the resultant external force vector, including external loads such as gravity,
 185 seepage force, seismic force, et al.; \mathbf{m}_{ext} denotes the moment \mathbf{f}_{ext} concerning \mathbf{r}_A . To
 186 integrate over the entire sliding surface dS :

$$187 \quad \iint_S d\mathbf{f} + \mathbf{f}_{ext} = \mathbf{0} \quad (12)$$

$$188 \quad \iint_S d\mathbf{m}_A + \mathbf{m}_{ext} = \mathbf{0} \quad (13)$$

189 According to Mohr-Coulomb criterion,

$$190 \quad \tau = \frac{1}{F_s} [c' + f'(\sigma - u)] = \frac{1}{F_s} (c_w + f' \sigma) \quad (14)$$

191 Here, F_s is the safety factor, c' and f' are the effective stress shear strength
 192 parameters, c' is cohesion, f' corresponds to the tangent of the friction angle, u is
 193 the pore pressure; c_w is defined as

$$194 \quad c_w \equiv c' - f' u \quad (15)$$

195 Order,

196
$$\mathbf{n}' = \begin{pmatrix} \mathbf{n} \\ \Delta \mathbf{r}_A \times \mathbf{n} \end{pmatrix}, \quad \mathbf{s}' = \begin{pmatrix} \mathbf{s} \\ \Delta \mathbf{r}_A \times \mathbf{s} \end{pmatrix}, \quad \mathbf{f}_m = \begin{pmatrix} \mathbf{f}_{ext} \\ \mathbf{m}_{ext} \end{pmatrix} \quad (16)$$

197 Substituting equations (10), (11), and (14) into equations (12) and (13), and
 198 merging into a more compact form:

199
$$F_s \left(\iint_s \mathbf{n}' \sigma dS + \mathbf{f}_m \right) + \iint_s (c_w + f' \sigma) \mathbf{s}' dS = 0 \quad (17)$$

200 **3.2 Normal stress expression of slip surface under seepage force and seismic force**

201 As shown with the dash line in Fig. 5, a vertical differential cylinder is now taken
 202 from the homogeneous sliding body from the slip surface to the slope surface. The load
 203 on the differential cylinder is shown in Fig. 6. $-kdw_1$ is the weight of the soil above
 204 phreatic surface, and $-kdw_2'$ refer to the floating weight of the soil below the phreatic
 205 surface. pdw_3 and edw_4 denote the seepage force and seismic force. dh refers to the
 206 action force of the soil around the differential cylinder.

207
 208 **Fig. 6 Sketch of force acting on a vertical differential cylinder in a sliding body**

209 Here, \mathbf{k} = unit vector of z -axis; \mathbf{p} = unit vector pointing to the direction of the
 210 seepage force; \mathbf{e} = unit vector pointing to the direction of the seismic force; θ = angle

211 between dS and the horizontal plane; ξ = angle between the phreatic surface dS^w and
 212 the horizontal plane in the differential cylinder.

213 The force equilibrium condition for a differential cylinder is

$$214 \quad \sigma n dS + \tau s dS - k dw_1 - k dw_2' + p dw_3 + e dw_4 + dh = 0 \quad (18)$$

215 Both sides of the Eq. (18) are simultaneously multiplied by \mathbf{n} to obtain

$$216 \quad \sigma = n_3 \left(\frac{dw_1}{dS} + \frac{dw_1'}{dS} \right) - n_p \frac{dw_3}{dS} - n_e \frac{dw_4}{dS} - \frac{\mathbf{n} \cdot d\mathbf{h}}{dS} \quad (19)$$

217 Here, n_3 = component of \mathbf{n} in the positive direction of z-axis, n_p = projection of
 218 \mathbf{p} in \mathbf{n} direction, n_e = projection of \mathbf{e} in \mathbf{n} direction.

219 Known,

$$220 \quad \begin{cases} dw_1 = \bar{\gamma} H_u dS \cos \theta \\ dw_2' = \bar{\gamma}' H_w dS \cos \theta \\ dw_3 = \gamma_w H_w dS \cos \theta \sin \xi \\ dw_4 = k_c (\bar{\gamma} H_u + \bar{\gamma}_{sat} H_w) dS \cos \theta \\ n_p = \mathbf{n} \cdot \mathbf{p} \\ n_e = \mathbf{n} \cdot \mathbf{e} \end{cases} \quad (20)$$

221 where, $\bar{\gamma}$ = average value of the unit weight of the soil above the phreatic surface; $\bar{\gamma}'$
 222 = average value for the unit floating weight of the soil below the phreatic surface; $\bar{\gamma}_{sat}$
 223 = average value of the unit saturated weight of below the phreatic surface; γ_w = unit
 224 weight of water; H_u = height of soil above the phreatic surface; H_w = height of the soil
 225 below the phreatic surface; k_c = seismic force coefficient.

226 Substitute Eq. (20) into Eq. (19) and sort it out

$$227 \quad \sigma = (\bar{\gamma} H_u + \bar{\gamma}' H_w) \cos^2 \theta - n_p \gamma_w H_w \cos \theta \sin \xi - n_e k_c (\bar{\gamma} H_u + \bar{\gamma}_{sat} H_w) \cos \theta - \frac{\mathbf{n} \cdot d\mathbf{h}}{dS} \quad (21)$$

228 Order

229
$$\sigma_0 = (\gamma H_u + \gamma' H_w) \cos^2 \theta - n_p \gamma_w H_w \cos \theta \sin \xi - n_e k_c (\gamma H_u + \gamma_{sat} H_w) \cos \theta,$$

230
$$h_n = -\frac{\mathbf{n} \cdot d\mathbf{h}}{dS}$$
 (22)

230 Therefore

231
$$\sigma = \sigma_0 + h_n$$
 (23)

232 Here, σ_0 = contribution of volume force to the normal stress. h_n = contribution
 233 of the force of surrounding soil to the normal stress of sliding surface.

234 The normal stress distribution of the slip surface can be approximated in the
 235 following (Zheng, 2009):

236
$$\sigma = \sigma_0 + f(x, y; \mathbf{a})$$
 (24)

237 where $f(x, y; \mathbf{a})$ = function in the horizontal coordinates (x, y) with a parametric
 238 vector \mathbf{a} consisting of five unknowns. $f(x, y; \mathbf{a})$ is constructed by piecewise triangular
 239 linear interpolation:

240
$$f(x, y; \mathbf{a}) = \mathbf{l} \mathbf{a}$$
 (25)

241 where \mathbf{l} is the interpolation function, $\mathbf{l} = (l_1, l_2, \dots, l_5)$, and it satisfies $\sum_{i=1}^5 l_i = 1$.

242

243 **Fig. 7** A triangular mesh for interpolation of normal stress on slip surface

244 As shown in Fig. 7, Ω_{xy} is the projection of the sliding body on the xoy plane, the
 245 area characterized by the dashed line. T_m is a triangular network containing 5 nodes.

246 $l_i(x, y) (i = 1, 2, \dots, 5)$ is the interpolation function for these 5 nodes, which can be

247 formed as in finite elements with the help of the area coordinates of the 4 triangles on
248 T_m .

249 Substitute Eq. (24) into Eq. (17), a system of nonlinear equations with F_s and \mathbf{a} as
250 unknowns is obtained:

$$251 \quad F_s \mathbf{B} \mathbf{a} + \mathbf{D} \mathbf{a} + F_s \mathbf{b} + \mathbf{d} = 0 \quad (26)$$

252 Where \mathbf{B} and \mathbf{D} are both matrices of order 6×5 , and \mathbf{b} and \mathbf{d} are both vectors of
253 order six, whose expressions are respectively.

$$254 \quad \begin{cases} \mathbf{B} = \iint_s \mathbf{n}' l dS \\ \mathbf{D} = \iint_s f' \mathbf{s}' l dS \\ \mathbf{b} = \mathbf{f}_m + \iint_s \sigma_0 \mathbf{n}' dS \\ \mathbf{d} = \iint_s (c_w + f' \sigma_0) \mathbf{s}' dS \end{cases} \quad (27)$$

255 We can solve Eq. (26) by either Newton's method or eigenvalue method.

256 In Eq. (26), all terms except the resultant external force (moment) \mathbf{f}_m are area
257 integrals. The volume integrals on the sliding body involved in the problem are
258 transformed into boundary integrals that can skip the column partitions. Hence, it is not
259 required to divide the sliding body into columns anymore, only the surface of the sliding
260 body needs to be partitioned, as detailed in Zheng (2007).

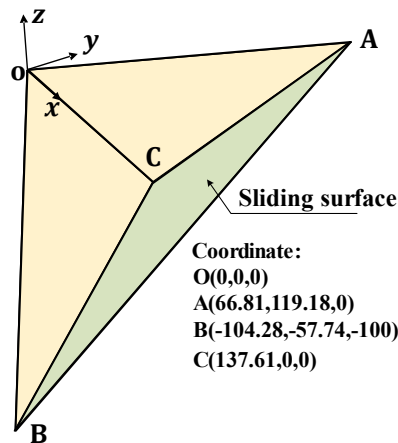

261 **4 Verification examples**

262 In order to verify the accuracy of the proposed method, two examples are analyzed
263 in this section. Different working conditions were set up for Example 2 and the results
264 are compared with those calculated by the software.

265 4.1 Example 1: translational sliding

266 Wedge stability in rock mechanics is a typical 3D limit equilibrium analysis
267 problem. Examples of wedge include two cases of geometric symmetry and asymmetry.
268 Example 1 is an asymmetric wedge. Fig. 8 shows the three-dimensional model and
269 geometric parameters of the wedge plane sliding. The sliding surface is composed of
270 two structural planes, ABC and OAB, and the coordinates of the vertices have been
271 listed in Fig. 8. The sliding direction of the wedge sliding body is assumed to be parallel
272 to the intersection line AB. The sliding surface of the wedge adopt the same shear
273 strength: $c' = 50\text{kPa}$ and $\phi' = 30^\circ$. The unit weight of the wedge is 26 kN/m^3 . For
274 simple wedges, the 3D limit equilibrium method has analytical solutions, but these
275 methods all include an assumption that the shear force on the bottom slip plane is
276 parallel to the intersecting prism. If the sliding direction of the wedge sliding body is
277 assumed to be parallel to the intersection line AB of the two structural planes, the wedge
278 sliding body is statically determinate, and the safety factor has an exact value of 1.640
279 (Hoek and Bray, 1977) for this example. The safety factor calculated based on the
280 method in this paper is 1.652. This discrepancy may stem from the triangulation of the
281 sliding surface. In our method, the sliding surface is approximated using a series of
282 small triangular elements, which might introduce a slight inaccuracy, leading to a minor
283 deviation in the calculated safety factor. However, we observed a slight difference
284 between exact value and the result obtained by the method proposed in our study, it
285 demonstrates that the proposed method can reasonably evaluate the stability of rocky

286 slopes containing different structural surfaces.

287

288 **Fig. 8 Model and geometric parameters of the wedge**

289 4.2 Example 2: ellipsoidal sliding

290 In order to verify the feasibility of the proposed method for calculating the slope
291 stability under seepage and earthquake, a classical ellipsoid example is selected for the
292 stability analysis, as shown in Fig.9, which is derived from the study of Zhang (1988).

293 Zhang's (1988) paper in 1988 provides a three-dimensional slope ellipsoid slip surface
294 example, and the simplified three-dimensional limit equilibrium method (only three
295 force equilibrium and one moment equilibrium are satisfied) is used for the stability
296 analysis. Zhang's (1988) solution for the 3D limit equilibrium of a symmetric ellipsoid
297 can be regarded as a rigorous solution since the ellipsoid has a symmetric sliding
298 surface and the other two moment equilibrium conditions are automatically satisfied by
299 the symmetric bar-column method. Zhang's (1988) solution has also been used by many
300 scholars to check the correctness of their own procedures (Hung et al., 1989; Huang
301 and Tsai, 2000; Zheng, 2009). The example is a homogeneous slope, the potential

302 sliding surface is a part of a simple ellipsoid, the sliding surface is symmetric about the

303 xoz plane, and the equation of the sliding surface is

304
$$\left(\frac{x-36.6}{24.4}\right)^2 + \left(\frac{y}{66.9}\right)^2 + \left(\frac{z-27.4}{24.4}\right)^2 = 1 \quad (26)$$

305

306 **Fig. 9** Model of ellipsoid example

307

308 **Fig. 10** Geometric parameters and middle profile with groundwater

309 The ellipsoid model is shown in Fig. 9. The external load of the slope is only
310 considered the effect of gravity, the unit gravity is 19.2kN/m^3 , and the effective shear
311 strength parameter: $c' = 29.3\text{kPa}$ and $\varphi' = 20^\circ$. We extended the analysis to include
312 complex conditions such as groundwater presence and seismic activity. Four working
313 conditions are considered in this section, case-1: no groundwater is considered as in the
314 computational model of Zhang (1988); case-2: groundwater is set up as shown in Fig.
315 10, the mechanical parameters are listed in Table 1; case-3: earthquake action in the

316 horizontal direction is considered; case-4: both groundwater and horizontal earthquake
 317 action are considered. Reference to the peak ground acceleration at the location of the
 318 real slope in the Three Gorges reservoir area in Section 5, the earthquake acceleration
 319 is taken 0.05g and the horizontal earthquake direction along the x-axis positive direction.
 320 The results from other methods and our proposed method are listed in Table 2.

321 **Table 1** Mechanical parameters of the slope

Unit weight, γ (KN/m ³)		Shear strength, c' (kPa)		Friction angle, ϕ' (°)	
Saturated condition	Unsaturated condition	Saturated condition	Unsaturated condition	Saturated condition	Unsaturated condition
21	19.2	15.8	29.3	13.5	20

322 Case-1: The safety factor calculated using our proposed method is 2.054, whereas
 323 Zhang (1988) obtained a result of 2.122 using the limit equilibrium method.
 324 Additionally, we perform a 2D stability analysis of the intermediate cross-section of the
 325 model using Rocscience's Slide software and obtain a safety factor of 2.084. Comparing
 326 the results mentioned above, it becomes evident that our proposed method for slope
 327 stability analysis is feasible, and its calculation results are consistent with the results
 328 obtained by using the traditional limit equilibrium method and two-dimensional
 329 stability analysis.

330 Case-2: Only the effect of groundwater seepage is considered. Mechanical
 331 parameters of the slope below the water surface adopt saturated, while above the water
 332 surface adopt unsaturated. The groundwater not only induces hydrodynamic effects, but
 333 also increases the saturation of geotechnical materials, leading to a reduction in soil

334 shear strength. In this working condition, the calculated safety factor is 1.183, which is
335 close to 1.057 calculated by Rocscience's Slide.

336 Case-3: We only consider the effect of horizontal earthquake on slope stability. In
337 order to compare the results with the 2D stability calculations, we choose the horizontal
338 seismic action direction to be in the xoz plane. The results calculated by the 3D
339 procedure and the 2D software are 1.855 and 1.861, respectively. Compared with the
340 case-2, the effect of seepage on the slope stability is greater than that of seismic action.

341 Case-4: We considered both seepage and horizontal seismic effects. In this case,
342 the results calculated by 3D program and 2D software are 1.047 and 0.934 respectively.

343 **Table 2** Safety factor of Example 2

Method	Zhang (1988)	Slide(2D)	The proposed method
Case-1	2.122	2.084	2.054
Case-2	-	1.057	1.183
Case-3	-	1.861	1.855
Case-4	-	0.934	1.047

344 Based on the above calculation results, the comparison revealed minimal
345 differences across all four conditions (natural, with groundwater, with seismic loading,
346 and combined), indicating that the proposed method is also effective in assessing slope
347 stability under seepage and seismic actions.

348 5 A True 3D Slope

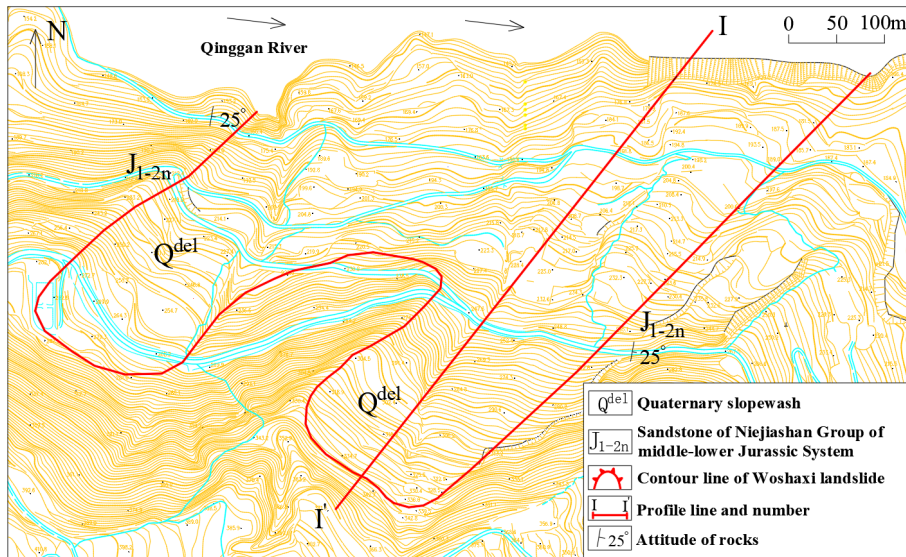

349 This section investigates slope stability evolution under the influence of rainfall
350 and earthquake by taking an actual slope in the Three Gorges reservoir as a case study.

354

Fig. 12 Contour map of Woshaxi slope

355

356

Fig. 13 Geological section map of Woshaxi slope

357

Fig. 11 provides a depiction of the Woshaxi landslide's geographical setting. Fig.

358 12 shows a topographic map of Woshaxi slope with contour lines and the cross-section
359 (I-I') of the landslide is illustrated in Fig. 13. This landslide is located on the right bank
360 of the Qinggan River, a Yangtze River tributary, and lies about 1.5km away from the
361 Qianjiangping landslide situated on the river's opposite bank. The composition of the
362 Woshaxi landslide primarily consists of rubble and soil, underlain by Jurassic-era
363 sandstone and mudstone layers that are interstratified. The orientation of these rock
364 layers is $100^{\circ} \angle 25^{\circ}$. The landslide has experienced significant impact due to water level
365 fluctuations in the range of 145-175m, resulting in submersion of its frontal part by
366 about 20-50m. This geological structure displays a descending gradient from the
367 southwest to the northeast, with a general gradient of 20° . The highest point at the rear
368 reaching an elevation of 405m, and the front edge descending below 140m. The
369 landslide encompasses an average thickness of around 15m and a total volume
370 estimated at $4.2 \times 10^6 \text{ m}^3$. Its main sliding direction of the landslide body is toward
371 east of north.

372 According to the Seismic Ground Motion Parameter Zonation Map of China, the
373 peak ground motion acceleration in this region is 0.05g. To investigate slope stability
374 evolution under seismic conditions, peak accelerations are calculated and analyzed at
375 various levels. The most dangerous case is considered in the following calculations,
376 where the direction of the horizontal seismic action coincides with the primary sliding
377 direction. The precipitation pattern in this region is characterized by relatively
378 concentrated temporal and spatial distribution. Most of the rainfall occurs between

379 April and October. To investigate the stability of three-dimensional slopes under the
 380 combined influence of rainfall and earthquake, this study considers the effects of three
 381 geotechnical parameters: permeability coefficient, porosity, and saturation. The
 382 proposed method is applied to calculate changes in slope stability resulting from
 383 average monthly rainfall and earthquake occurring between 2007-2009.

384

385 **Fig. 14 Average monthly rainfall from 2007 to 2009**

386 Fig. 14 shows the average monthly rainfall from 2007 to 2009. Table 3 lists the
 387 physical and mechanical parameters of the landslide body. It is assumed that the
 388 reservoir water level remains unchanged. To assess the effects of different geotechnical
 389 parameters and seismic action on the safety factor, four cases are considered: (i) rainfall
 390 only, (ii) rainfall and horizontal earthquake, (iii) rainfall and vertical earthquake, and
 391 (iv) rainfall and earthquake in both horizontal and vertical directions.

392

22.4	20.8	18	22	15	20
------	------	----	----	----	----

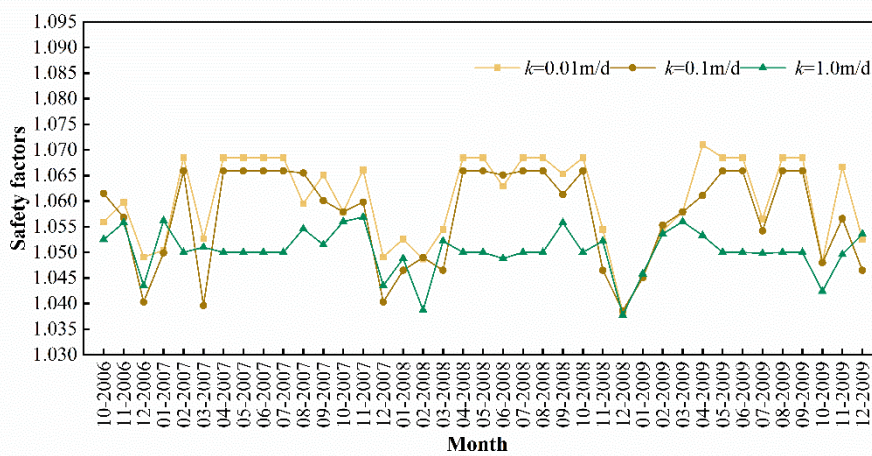

393 (i) Rainfall only

394 The three parameters, infiltration coefficient, porosity, and saturation, have
 395 different effects on the safety factor of slopes. The safety factor varies with the monthly
 396 rainfall. The analysis indicates that an increase in rainfall does not invariably lead to a
 397 decrease in the safety factor of the slope. This phenomenon can be attributed to the fact
 398 that increased rainfall raises the phreatic surface within the slope, affecting two key
 399 aspects: firstly, it enhances the hydrodynamic forces, and secondly, it increases the
 400 pressure at the base of the slope. When the increase in pressure at the slope's base has
 401 a more pronounced impact on stability than the hydrodynamic forces, the safety factor
 402 of the slope will subsequently increase. Conversely, if the hydrodynamic forces
 403 dominate, the stability of the slope will diminish. As shown in Fig. 15(a), the
 404 permeability coefficient k is 0.01, 0.1 and 1m/d, respectively. With other parameters
 405 unchanged, the trend of safety factor variation for Woshaxi landslide is consistent. The
 406 higher the permeability coefficient, the greater the soil's ability to allow water to pass
 407 through above the phreatic surface, the smaller the rise of the phreatic surface within
 408 the slope. This results in a smaller increase in pressure at the foot of the slope and a
 409 lower safety factor.

410 As shown in Fig. 15(b), the porosity n is 0.1, 0.3 and 0.5, respectively, and the
 411 safety coefficient of the Woshaxi landslide is consistent under the condition that other
 412 parameters remain unchanged. The higher the porosity, the greater the soil permeability
 413 above the phreatic surface, the smaller the rise of the phreatic surface within the slope,

414 resulting in a smaller increase of pressure at the slope's foot and thus a lower safety
 415 factor.

416 As shown in Fig. 15(c), the saturation S_r of the soil above the phreatic surface of
 417 the landslide is 0.4, 0.6 and 0.8, respectively, and the safety factor of the Woshaxi
 418 landslide is consistent under other parameters remained unchanged. The higher the
 419 saturation, the lower the permeability of soil above the phreatic surface, resulting in a
 420 greater rise of phreatic surface within the slope and an increased pressure at its foot,
 421 thereby leading to a higher safety factor. Overall, under rainfall conditions, soil porosity
 422 on the phreatic surface has a greater impact on safety factor than permeability
 423 coefficient and saturation.

(b) porosity

428

429

(c) saturation

Fig. 15 Safety factors of the Woshaxi landslide under rainfall

431

(ii) Rainfall and horizontal earthquake

432

Fig. 16 shows the evolution of the stability of the Woshaxi landslide under the

433

combined effect of rainfall and horizontal earthquake with different geotechnical

434

parameters, and the horizontal earthquake coefficient k_h is taken as 0.05. Comparing

435

with Fig. 15, it can be observed that after considering the effect of horizontal earthquake,

436

the variation trend of the safety factor of the Woshaxi landslide calculated with different

437

geotechnical parameters is consistent with that under the rainfall condition only, but the

438 stability of the landslide is obviously decreased. Fig. 17 shows the evolution of the
439 stability of the Woshaxi landslide with rainfall and different horizontal earthquake
440 coefficients. With other parameters unchanged, the values of the horizontal earthquake
441 coefficients are 0.05, 0.1 and 0.15 respectively. In this research, we employed three
442 different horizontal earthquake coefficients: 0.05, 0.1, and 0.15. The coefficient of 0.05
443 is based on the seismic zoning map of China, corresponding to the seismic
444 characteristics and expected level of seismic activity in the study area. As for the other
445 two coefficients, 0.1 and 0.15, they are not directly associated with any specific
446 earthquake magnitude or return period. These values were set based on engineering
447 requirements and safety considerations, aiming to assess the variation in slope stability
448 under stronger seismic actions. This approach allows us to understand the response of
449 the slope under different seismic intensities and provides a safety margin for seismic
450 activities that may exceed expectations. Our study has revealed that within the specific
451 context of the examined landslide, as the horizontal earthquake coefficient increases,
452 there is a notable decrease in the safety factor. It is also observed that in this particular
453 case, the impact of seismic activity on slope stability appears to be considerably more
454 pronounced than that of rainfall. However, these findings are derived from a singular
455 case study, focusing on a specific landslide morphology and set of soil properties.
456 Consequently, they may not necessarily be universally applicable across different
457 landslide types and varying geological conditions.

465

earthquake ($k_h = 0.05$)

466

467 **Fig. 17 Safety factors of the Woshaxi landslide under rainfall and horizontal**
 468 **earthquake (different horizontal seismic coefficient)**

469 (iii) Rainfall and vertical earthquake

470 Fig. 18 shows the evolution of the stability of the Woshaxi landslide with rainfall
 471 and different vertical earthquake coefficients. With other parameters unchanged, the
 472 vertical earthquake coefficient k_v takes on values of 0.025, 0, and -0.025 respectively,
 473 and the negative sign indicates that the direction of vertical earthquake is vertically
 474 downward. It is obvious from Fig. 18 that the corresponding safety factor when the
 475 earthquake acts vertically downward is smaller than the corresponding safety factor
 476 when it is vertically upward.

477

478 **Fig. 18** Safety factors of the Woshaxi landslide under rainfall and vertical earthquake

479 (iv) Rainfall and earthquake in both horizontal and vertical directions

480 Fig. 19 shows the evolution of the stability of the Woshaxi landslide with rainfall
481 and different earthquake coefficients. Horizontal earthquake coefficient k_h is taken as
482 0.05, and the values of vertical earthquake coefficient are 0.025, 0, -0.025 respectively,
483 and the negative sign indicates that the direction of vertical earthquake action is
484 vertically downward. Under the condition that other parameters remain unchanged, the
485 slope stability is lower when considering both horizontal and vertical upward
486 earthquake compared to considering only horizontal earthquake. Therefore, it is
487 essential to properly account for the effect of vertical earthquake in order to ensure
488 maximum safety.

489

490 **Fig. 19** Safety factors of the Woshaxi landslide under rainfall and earthquake (in both

491 horizontal and vertical directions)

492 6 Conclusions

493 In this paper, the calculation of the seepage force is studied, the normal stress
494 expression on the sliding surface of a slope under seepage force and seismic force are

495 also derived. Furthermore, a global analysis method that considers both seepage and
496 seismic forces is proposed to determine the safety factor of slopes subjected to the
497 combined effect of rainfall and earthquake. The reliability of the proposed method is
498 also verified with two examples combining software calculations and previous results.

499 Taking a slope in the Three Gorges reservoir area as an example, this study
500 investigates the influence of soil permeability coefficient, porosity and saturation on
501 slope stability, and analyzes the safety evolution of this slope under combined effects
502 of rainfall and earthquake. The results indicate that, under rainfall conditions, the
503 porosity of the soil above the phreatic surface exerts a greater influence on safety factor
504 than permeability coefficient and saturation. With an increase in the horizontal
505 earthquake coefficient, the safety factor of the landslide is significantly reduced, and
506 the impact of earthquake on slope stability surpasses that of rainfall. The safety factor
507 corresponding to vertical downward earthquake action is smaller than that of vertical
508 upward, and the stability of slope is lower when considering horizontal and vertical
509 upward earthquake actions. Therefore, in order to ensure maximum safety, proper
510 consideration should be given to vertical earthquake actions.

511 When considering rainfall alone, the slope safety factor is 1.04-1.09, positioning
512 the slope in a state that between unstable and basically stable. However, upon
513 accounting for horizontal seismic activity, the slope safety factor decreases to about 0.9
514 and is transformed into an unstable state. When the vertical earthquake is considered,
515 the slope safety factor is 1.035-1.075. This represents a slight reduction but still in the

516 unstable and basically stable state. This suggests that horizontal seismic influences
517 exert a more pronounced impact on slope stability compared to vertical. When rainfall
518 and earthquake act simultaneously, the safety factor calculated using the proposed
519 method falls below 1.0, indicating an unstable condition where landslide disasters are
520 likely to occur on the slope. The research results provide scientific basis for slope
521 stability analysis and prevention. Further, the proposed method can identify potential
522 risk areas for landslide hazards, and planners in the Three Gorges Reservoir area can
523 better consider these risks and take measures to increase the seismic and flood resilience
524 of reservoir infrastructure.

525 **Data availability**

526 The data used in this study are available from the first author upon request.

527 **Author contribution**

528 JW analyzed the data, conceived the paper, and wrote the paper; ZW conceived
529 and co-wrote the paper; HL reviewed and improved the analysis and paper; and GS
530 provided the data of the actual slope in the Three Gorges reservoir.
