20 **Abstract.** The Central Volcanic Zone of the Andes (CVZA) extends from southern Peru, through the altiplano of Bolivia, to Puna ~~de Atacama~~ of northern Chile and Argentina, between latitudes 14-28°S of the Andean cordillera, with altitudes raising up to more than 4,000 m above sea level. Given the large number of active volcanoes in this area, which are often located close to both urban areas and critical infrastructure, prioritization of volcanic risk reduction strategies is crucial. ~~However, the~~The identification of hazardous active volcanoes is challenging due to the limited accessibility, ~~scarce historical record, and the~~ difficulty in identifying relative or absolute ages due to the extreme arid climate. Here, we identify the riskiest highest risk volcanoes based on combining complementary strategies including: i) a regional mapping based on volcanic hazard parameters and surrounding density of elements at risk combined with and ii) the application of the recently developed Volcanic Risk Ranking (VRR) methodology that integrates hazard, exposure and vulnerability as factors that increase risk, and resilience as a factor that reduces risk. The method identifies We identified 59 active and potentially active volcanoes that not only highlight include the volcanic centers centres with the most intense and frequent volcanic eruptions (e.g., El Misti and Ubinas volcanoes (Peru) and) but also the highest density of exposed elements (e.g., the cities of Arequipa and Mequegua (Peru), but also). VRR is carried out for 19 out of 59 volcanoes, active within the last 1,000 years or with unrest signs, highlighting those with the highest potential impact requiring risk mitigation actions (i.e., Cerro Blanco (in Argentina), and Yucamane, Huaynaputina, Tutupaca, and Ticsani (in Peru)) and requiring risk mitigation actions to improve the capacity to face or

35 overcome a disaster (e.g., volcanic hazard and risk/impact assessments, monitoring systems, educational activities, and
implementation of early warning systems).

1 Introduction

40 The Central Volcanic Zone of the Andes (CVZA) is one of the most active volcanic zones in South America where most
volcanoes are located within 25 km of an international border, comprising Argentina, Chile, Bolivia and Peru, implying
significant transboundary challenges (Donovan and Oppenheimer, 2019). Moreover, in this region, volcanoes are located on
the Altiplano-Puna plateau and, therefore, several of them are higher than 6,000 m above sea level (a.s.l), including Ojos del
Salado, which is the highest volcanic summit in the world (Amigo, 2021). The CVZA has been studied over the years to
investigate a wide number of geological processes (e.g., geologic evolution, volcanic arc segmentation, magma genesis), but
due to the difficult access, historical records of eruptions were limited until very recently (Aguilera et al., 2022). Systematic
volcanological studies in the CVZA started in the 1970-80s headed by Chile (e.g., Francis et al., 1974, 1985; Gonzalez-Ferran
et al., 1985; de Silva, 1989; Gardeweg and Amigo, 2015), followed by Argentina in the 1980-90s (e.g., Viramonte et al., 1984,
1994; De Silva and Francis, 1991; Coira and Kay, 1993; Martí et al., 1999; Perucca and Moreiras, 2009), Peru in the 1990s
(e.g., Thouret et al., 1994, 1999; Mering et al., 1996; Fidel et al., 1997; De Silva and Zielinski, 1998; Traversa et al., 2011),
and finally by Bolivia in the Western Cordillera and Altiplano at the beginning of the 21st century (e.g., Wörner et al., 2000;
55 Sparks et al., 2008; Mamani et al., 2010; Ward et al., 2013; Michelfelder et al., 2014; Comeau et al., 2016). Given the proximity
of a large number of volcanoes to urban areas and critical infrastructure, the identification of the riskiest volcanoes and,
therefore, the implementation of volcanic risk reduction strategies are especially important for the CVZA. Furthermore, during
the last 20 years, volcanic unrest in various areas of the CVZA has motivated the implementation of new monitoring
capabilities and research investments that currently promote cross-border collaborations (Aguilera et al., 2022).

Three of the four countries of the CVZA have already produced a relative volcanic threat ranking, Peru (Macedo et al., 2016),
Chile (Lara et al., 2006; Ranking de riesgo específico para volcanes activos de Chile 2019; Ranking de riesgo específico para
volcanes activos de Chile 2023) and Argentina (Elisondo et al., 2016; García et al., 2018; Elisondo and Fariás, 2023), based
on the methodology proposed by Ewert et al. (1998; 2005). Peru ranked 16 volcanoes with four levels of risk. The Central
60 Volcanic Zone of the Andes (CVZA) is one of the four active volcanic zones in South America (Fig. 1). This zone within the
latitudes 14-28°S comprises at least two volcanic segments controlled by a compressive subduction tectonics, with a diffuse
boundary at 21°S between Isluga and Irruputuncu volcanoes. The northern CVZA segment, located in southern Peru, has major
volcanoes aligned in a NW-SE direction and is characterized by significant historic magmatic eruptions. The southern segment
within northern Chile, south-western Bolivia, and north-western Argentina on the other hand, has a more northerly trend
65 comprising older edifices that have existed for more than a million years (e.g., Ollagüe, with a history going back as far as
800,000 years) and have longer repose periods (De Silva and Francis, 1991). The CVZA has an ongoing volcanism since the

Late Eocene-Early Oligocene, comprising a wide diversity of activity patterns, volcanic forms, products, and magma compositions (e.g., Bertin et al., 2022a; Grosse et al., 2018, 2022), including catastrophic cone collapses and a long record of voluminous silicic pyroclastic activity associated to potentially active giant ignimbrite centres and caldera systems with important implications for the safety of nearby communities (Stern, 2004).

The lack of knowledge due to scarce historical records and difficulty in identifying deposit ages together with its proximity to four geographical borders imply significant challenges for the CVZA, making it an area of interest for volcanic risk reduction. In fact, systematic studies of the CVZA only started in the 1970-80s, and increased during the last 20 years motivated by the implementation of new monitoring capabilities and research investments as a response to volcanic unrest in various areas, currently promoting cross-border collaborations (Aguilera et al., 2022; Forte et al., 2021). However, the characterization of hazardous active volcanoes is very challenging because of their limited accessibility. Several CVZA volcanoes are higher than 6,000 m above sea level (a.s.l.), including Ojos del Salado, which is the highest volcanic summit of the world (Amigo, 2021). In addition, the extreme dry and arid conditions further complicate detailed studies of these volcanoes. As an example, the determination of the relative ages through morphology is difficult due to very low erosion rates making difficult the distinction between old and fresh volcanic features. Existing radiocarbon techniques are also limited because sediments contain small amounts of organic carbon (Gillespie et al., 1991; De Silva and Francis, 1991). Finally, the CVZA volcanoes are located within 25 km of an international border, in between Argentina, Chile, Bolivia or Peru. Andean communities have interacted with these volcanic features for more than 11,000 years even before border delineation (Ramos Chocobar and Tironi, 2022; Loyola et al., 2022). However, the current division of borders increases the challenges of volcanic risk management since each country has multiple strategies, resources, sovereignty and intrinsic socio-economic and political conditions playing a key role when facing natural risks (e.g., Donovan and Oppenheimer, 2019; Petit-Breuilh Sepúlveda, 2016; Romero and Albornoz, 2013).

One of the major difficulties within the CVZA lies in the identification of active hazardous volcanoes. Although various nomenclatures have been proposed to describe the state of a volcano (e.g., Szakács, 1994; Auker et al., 2015), here we stick to Szakács definition, also in agreement with the Geological Services of Argentina (SEGEMAR), Chile (SERNAGEOMIN), and Peru (INGEMMET). According to Szakács (1994) "active volcano" and "extinct volcano" are mutually exclusive terms. Active volcanoes are geologically active when they had at least one eruption in the Holocene period, then, they can be subdivided into "erupting" and "dormant" types based on their current state of activity, while extinct volcanoes could be classified as "young" or "old" using criteria such as the extent of erosion or geochronological age. The term "potentially active" is reserved for those fresh-looking volcanoes lacking both documented eruptions and reliable datations. "Potentially active" volcanoes could be defined as "active-dormant" or "extinct-young" volcanoes as more information becomes available (Szakács, 1994). Alternatively, in absence of data of eruptions during the Holocene, a volcano can be considered "potentially active" when it presents visible signs of unrest activity such as degassing, seismicity or ground deformation (e.g., Simkin and Siebert, 1994; Ewert et al., 2005; Ewert, 2007; Lara et al., 2011). As a result, in this study we analyse a total of 59 volcanoes, 25 active

Holocene volcanoes and 34 potentially active volcanoes having fresh volcanic morphology or records of at least one sign of unrest (i.e., seismicity, deformation or degassing).

Volcanic rankings have been used to identify threatening volcanoes, notably based on the strategy proposed by Ewert et al. (1998; 2005; 2007), that combines hazard (the destructive natural phenomena produced by a volcano) and exposure (people and property at risk from the hazards) parameters. Based on this methodology, three of the four countries of the CVZA have already produced a relative volcanic threat ranking considering the whole country (e.g., Macedo et al., 2016; Lara et al., 2006; SERNAGEOMIN, 2020, 2023; Elissondo et al., 2016; García et al., 2018; Elissondo and Fariás, 2024). Peru ranked 16 volcanoes with four levels of threat, from very low to very high (Macedo et al., 2016). Chile and Argentina, recently updated their relative volcanic risk rankings ranking with 87 active and potentially active volcanoes based on 13 hazard and 12 exposure parameters (SERNAGEOMIN, 2023). A new volcanic risk ranking for Argentina was also recently published with 38 active and potentially active volcanoes, respectively, (Ranking de riesgo específico para volcanes activos de Chile 2023; Elissondo and Fariás, 2023). Both divided in five categories of relative risk (from low to very high), and the latter based on 15 hazard parameters including the type of volcano, the frequency and magnitude of eruptions, the products emitted in the Holocene, and the historical factors of unrest. Ten and 10 exposure parameters were also considered including population, local and regional aviation, transportation and energy infrastructure.

A new (Elissondo and Fariás, 2024). From these rankings only 26 (Chilean ranking) and 22 (Argentinian ranking) volcanic centres are part of the CVZA. However, many active and potentially active volcanoes of the CVZA and their eruptive histories remain understudied. Recently, a new Volcanic Risk Ranking (VRR) methodology was recently proposed, expanding the work of Ewert et al. (1998; 2005) by integrating additional factors that can influence the risk level (i.e., vulnerability and resilience). Ewert et al. (1998; 2005), by integrating additional factors that can influence the risk level, i.e., vulnerability, as characteristics of the elements at risk that can increase the susceptibility to the impact of a natural hazard; and resilience, as the system's ability to adapt to changes, overcome disturbances and maintain functionality from the effects of a hazard (Nieto-Torres et al., 2021; Guimarães et al., 2021). This new VRR methodology was tested on Mexican volcanoes with activity recorded in the last 10,000 and 1,000 years (Nieto-Torres et al., 2021) and for the applied to Latin American volcanoes with activity recorded in the last 1,000 years (Guimarães et al., 2021).

In this study, we identify the volcanoes of the CVZA with the highest potential impact based on two complementary strategies: i) the regional mapping of hazard parameters and elements at risk, and ii) the new VRR methodology (Nieto-Torres et al., 2021).

In this study, we identify the volcanoes of the CVZA with the highest potential impact based on two complementary strategies: i) the regional mapping of hazard parameters and elements at risk for a total of 59 active and potentially active volcanoes, and ii) the VRR methodology proposed by Nieto-Torres et al., (2021) for 19 volcanoes considered more likely to have an eruption

135 in the future. Our study underlines two main aspects. First, it demonstrates the challenges of regional risk assessment,
especially for cross-boundary volcanoes managed by multiple institutions and associated with different geographical contexts.
140 Second, the combination of multiple risk factors (hazard, exposure, vulnerability and resilience) provides fundamental insights
for risk management. Indeed, the regional mapping and regional VRR provides the opportunity to consider transboundary
volcanoes that are often neglected by local authorities, typically more focused on active volcanoes with short repose intervals,
or those that lack any resilience measures.

2 Geological setting of the CVZA

The Andean Cordillera started building during the late Paleozoic, characterized by an important magmatism associated with the beginning of the subduction in the Pacific margin (Ramos and Aleman, 2000; Tilling, 2009). ~~The most significant events in the evolution of the Andes occurred after the breakup of the Farallon plate into the Cocos and Nazca plates in the Late Oligocene (~ 27±2 Ma) that caused changes in subduction geometry, and accelerated crustal shortening, thickening and uplift in the Northern and Central Andes (Jaillard et al., 2000; Ramos and Aleman, 2000; Jordan et al., 1983; Sempere et al., 1990). The resulting increase in convergence rates drove the magmatic activity along the whole Andean chain. The most significant events in the evolution of the Andes occurred after the breakup of the Farallon plate into the Cocos and Nazca plates in the Late Oligocene (~ 27±2 Ma) that caused changes in subduction geometry, and accelerated crustal shortening, thickening and uplift in the Northern and Central Andes (Jaillard et al., 2000; Ramos and Aleman, 2000; Jordan et al., 1983; Sempere et al., 1990; Hall et al., 2008). The resulting increase in convergence rates drove the magmatic activity nearly all along the Andean ridge (Stern, 2004). Several studies discuss the Andean volcanic arc, Andean magmatism and associated volcanism (e.g., Jaillard et al., 2000; Ramos and Aleman, 2000; Stern, 2004; Hall et al., 2008). Although many of the main features of the Andes were formed during the Miocene, neotectonic deformation significantly modified the topography, controlled the location of active volcanoes and thus the distinction among small arc segments within larger volcanic zones. Although many of the main features of the Andes were formed during the Miocene, neotectonic deformation significantly modified the topography, controlled the location of active volcanoes and thus the distinction among small arc segments within the main volcanic zones (Stern, 2004). A total of 204 out of the 1500 active volcanoes during the Holocene worldwide are part of the Andes, but their distribution is not continuous along the Andean margin (Tilling, 2009). Four segments can be identified (Fig. 1): the Northern Volcanic Zone of the Andes (NVZA) from Colombia to Ecuador; the Central Volcanic Zone of the Andes (CVZA) along southern Peru, northern Chile, southwestern Bolivia, and northwestern Argentina; the Southern Volcanic Zone of the Andes (SVZA) extending from central to southern Chile and Argentina; and finally, the Austral Volcanic Zone of the Andes (AVZA), along the southernmost region of the continent. These segments are separated from each other by volcanically inactive gaps that may also be a result of changes in the slabs dip (e.g., Barazangi and Isaacs, 1976; Thorpe, 1984; Pilger, 1984; Stern, 2004; Tilling, 2009).~~

Formatted: German (Germany)

170 . A total of 204 out of the 1500 active volcanoes during the Holocene worldwide are part of the Andes, but their distribution
is not continuous along the Andean margin (Tilling, 2009; GVP, 2023a). Four main zones can be identified (Fig. 1): the
Northern Volcanic Zone of the Andes (NVZA) from Colombia to Ecuador; the Central Volcanic Zone of the Andes (CVZA)
175 along southern Peru, northern Chile, south-western Bolivia, and north-western Argentina; the Southern Volcanic Zone of the
Andes (SVZA) extending from central to southern Chile and Argentina; and finally, the Austral Volcanic Zone of the Andes
(AVZA), along the southernmost region of the continent. These segments are separated from each other by volcanically
inactive gaps that may be a result of the subduction of the Nazca and Juan Fernandez ridges, which is an important factor
controlling the geometry of Andean flat-slabs (e.g., Barazangi and Isacks, 1976; Thorpe et al., 1984; Pilger, 1984; Stern, 2004;
Tilling, 2009; Kay and Coira, 2009).

180 The CVZA, the aim of this study, is located between latitudes 14° and 28°S of the Andean cordillera, between the Peruvian
and Pampean flat-slab segments (Fig. 1). Almost all the volcanoes in this zone are above 4,000-5,500 m a.s.l., constituting
a high, remote, and exceptionally arid region (De Silva and Francis, 1991). It is formed by the subduction of the Nazca Plate
below the South American Plate at a convergence rate of 7-9 cm/ per year and an angle of 30° to the trench (Cahill and Isacks,
1992; Hayes et al., 2018; Gianni et al., 2019). The continental crust in the CVZA reaches a thickness of up to 65-70 km, (James,
1971; Van der Meijde et al., 2013), composed of Cenozoic volcanic rocks overlying a 2000-2,000 Ma basement in the northern
part and Late Precambrian-to-Paleozoic substrate in the southern segment (Walker et al., 2013). Andesites, dacites and
185 rhyolites are the dominant rock types erupted composition in the CVZA, although basaltic andesites and occasional basalts
occur. The most relevant volcanic hazards in of the Central Andean volcanoes include tephra fallout, pyroclastic density
currents, ballistics, lava flows and lava domes, debris flows, and lahars (Bertin et al., 2022a).

3 Methodology

This study includes the analysis of volcanoes in the four countries prone to be impacted by future volcanic activity inof the CVZA (i.e., Peru, Bolivia, Argentina and Chile) ~~for which four~~. Four main steps were carried out: 1) update of the inventory compilation of active and potentially active volcanoes of the CVZA based on the existing catalogs/catalogues of De Silva and Francis (1991), GVP (2013), Macedo et al. (2016), ~~SERNAGEOMIN (2023)~~(2016), ~~SERNAGEOMIN (2023)~~, ~~Elissondo and Farias (2023)~~Elissondo and Farias (2023) and Aguilera et al. (2022), ~~and compilation including a detailed review of hazard and resilience parameters (Reyes-Hardy et al., 2023)~~; 2) compilation of elements at risk, available in Reyes-Hardy et al. (2023); 2) identification of elements at risk (e.g., population, transportation and critical facilities); 3) regional mapping that includes both volcanic hazard parameters/features and surrounding elements at risk; 4) for all the 59 active and potentially active volcanoes of the CVZA; 4) application of the VRR methodology (Nieto-Torres et al., 2021) to identify the riskiest volcanoes of the CVZA.

The regional mapping was achieved using all active and potentially active volcanoes identified for the CVZA, whereas the VRR methodology was applied to the highest risk volcanoes that had at least one eruption in the last 1,000 years, following Guimarães et al., (2021), in addition to the volcanoes with Pleistocene or Holocene of the CVZA based on the estimation and scoring of hazard, exposure, vulnerability and resilience parameters. This last step focus on volcanoes having shown a volcanic activity but currently showing 3 types of during the past 1,000 years or records of the three signs of unrest signals (i.e., seismic activity, ground deformation and degassing).

3.1 Identification of active and potentially active volcanoes of the CVZA

The first challenge in ranking the risk amongst volcanoes in a specific area is the selection of volcanoes to consider. Since geochronological data or preserved historical records are largely absent in the CVZA, the term "potentially active" has been widely used to account for this lack of data. ~~3.1 Identification of active and potentially active volcanoes of the CVZA~~

The first challenge in ranking the risk amongst volcanoes in a specific area is the initial selection of the active and potentially active volcanoes to consider. This is especially important for the CVZA because of the lack of geochronological evidence and/or preserved historical records for most volcanoes (Lara et al., 2021; Bertin et al., 2022a). Therefore, the first step of our study was the identification of the volcanoes of the CVZA based on a comprehensive analysis of 6 catalogs (i.e., De Silva and Francis, 1991; GVP, 2013; Macedo et al., 2016; SERNAGEOMIN, 2023; Elissondo and Farias, 2023; Aguilera et al., 2022). The identification and compilation of hazard and resilience parameters of the CVZA volcanoes included all Holocene volcanoes as well as Pleistocene volcanic centers that show unrest signs and/or fresh volcanic morphological features. Hazard and resilience parameters used for both the regional map and VRR are detailed in Supplementary material 1, based on Reyes-Hardy et al. (2023).

This has led to discrepancies in the CVZA volcano count evidenced in the number of potentially active eruptive centres identified by the “Volcanoes of the Central Andes” (n=73; De Silva and Francis, 1991), the Global Volcanism Program database (n=67; GVP, 2013), as well as within different catalogues accounting for CVZA volcanoes (i.e., Elissondo et al., 2016; SERNAGEOMIN, 2020; Aguilera et al., 2022; Macedo et al., 2016; SERNAGEOMIN, 2023; Elissondo and Farias, 2024). The first step of our study was the compilation of the active and potentially active volcanoes of the CVZA based on a comprehensive analysis of 6 catalogues in collaboration with SEGEMAR, SERNAGEOMIN, and INGEMMET, combined with their own updated volcanic risk rankings relative for each country (i.e., Argentina, Elissondo and Farias, 2024; Peru, Macedo et al., 2016; and Chile, SERNAGEOMIN, 2023). A total of 59 volcanic centres have been identified as active or potentially active, of which 50 have Holocene and 9 Pleistocene activity (Table 1). In terms of geographical distribution, 12 volcanoes are located in Chile, 9 in Argentina, 13 in the Chile-Argentina border, 7 in the Chile-Bolivia border, 2 in Bolivia and 16 in Peru. In terms of types of volcanoes, 34 are stratovolcanoes, 15 are volcanic complex, three are volcanic fields, one is a pyroclastic cone, four are dome complex, one is a maar and one is a caldera (Supplementary material 1). Among volcanoes with Holocene activity, 16 volcanoes had at least one eruption in the last 1,000 years. In addition, three volcanoes (one of Pleistocene and two of Holocene activity) with eruptions older than 1,000 years, showed records of all three signs of unrest (i.e., seismicity, ground deformation and degassing). The complexity associated with the definition of active and potentially active volcanoes of the CVZA highlights the challenging characterization of volcanoes in this area, including those with long repose interval and/or poor constrain of eruptive record. Although our volcano list is the best agreement of active and potentially active volcanoes of the CVZA, such a list can change depending on future knowledge of this zone including geochronology and monitoring studies.

Table 1. List of the active and potentially active volcanoes of the CVZA (extracted from Supplementary material 1). C.: Cerro, N.: Nevado (s), Pe: Peru, Ch: Chile, Bo: Bolivia, Ar: Argentina, H: Holocene, Pl: Pleistocene, DC: Dome complex, PC: Pyroclastic cone, ST: Stratovolcano, VF: Volcanic field, VC: Volcanic complex, S: Seismic unrest records, G: Ground deformation records, D: Fumarolic/magmatic degassing records, U: Unknown, and ND: No data. Notice that volcanoes with last eruption during the past 1,000 years and/or presenting records of all three signs of unrest are in bold.

Notice that if not indicated otherwise, the "Max VEI" and "N° Holocene eruptions" values correspond to the maximum VEI, and the number of eruptions and confirmed eruptions (in parenthesis) during the Holocene according to GVP (2013, 2023a).

3.2 Elements at risk

In this study, the elements at risk include population, residential buildings, critical infrastructure (e.g., transportation, power, water and telecommunication supply networks), emergency facilities (e.g., police and fire stations), critical facilities (e.g., government offices, schools), and economic activities (e.g., parks and protected areas, mines, salt pans, farmlands, industrial areas). Each dataset is country-specific, favoring official sources (e.g., ministries, national geographic institutes, national observatories, statistical institutes). Open-source datasets (e.g., HOT, 2020) were used to complete missing official information. All details and sources of elements at risk are available in Supplementary material 2.

Concerning the population, density data are provided by WorldPop - Open Spatial Demographic Data and Research (WorldPop, 2018). Worldpop data used in this study represent the spatial distribution of resident population density in 2020 per grid-cell (inhabitants per km²), and they are provided at country level (i.e., Peru, Bolivia, Argentina, and Chile), with a resolution of about 1 km. They are obtained 30 arc seconds (approximately 1 km at the equator). Obtained from the so-called top-down unconstrained modelling (WorldPop, 2023). However, this method misplaces the population in some places indicating locations showing the presence of people in uninhabited areas (WorldPop, 2023). We corrected the error of validation with satellite images was used to correct and reclassify the discrepancies with non-zero population using mainly satellite images and we reclassified the pixels into the range of 0-0.1 inhabitants per km². This data correction of data allowed us to obtain results of population density that were more consistent with the density and distribution of population and residential buildings populated centres (see Supplementary material 2). National censuses were used to extract socio-economic data required to constrain the VRR exposure parameters (IGN, 2010; INDEC, 2010; INE, 2012, 2017a, 2017b; INEI, 2017; IDE, 2021; ONEMI, 2021a, 2021b).

3.3 Regional mapping

315 The regional mapping step consists in combining volcanic hazard parameters/features and elements at risk, representing a first-order analysis of volcanoes that could have a potential impact in the region. In terms of hazard parameters, the number of eruptions and the maximum VEI during the Holocene have been represented as well as the age of ~~the volcanoes~~ their last

increasing population density, telecommunication facilities; and updated multiple economic activities). Each risk factor (i.e., hazard, vulnerability, exposure and resilience) was normalized to the maximum possible score and multiplied by the value of 10, to guarantee the same weight. Therefore, the scores were normalized based on the maximum possible value for each of the evaluated factors (19 for hazard, 48 for exposure, 95 for vulnerability, and 18 for hazard, exposure, vulnerability, and resilience, respectively). The maximum hazard score represents the highest intensity of each volcanic process; the maximum exposure score is the largest quantity of elements/assets prone to be affected; and the maximum vulnerability score, represents the highest level of susceptibility to damage or loss. In contrast, the maximum resilience score represents the maximum level of capacity to face or overcome a disaster (Nieto-Torres et al., 2021). Each risk factor was normalized to the maximum possible score and multiplied by the value of 10, to guarantee the same weight for each risk factor. For VRR (2), the value of 1 is added after the aggregation of resilience parameters, before normalization (Nieto-Torres et al., 2021).

4. Results

4.1 Active and potentially active volcanoes of the CVZA

From our detailed analysis of the existing catalogs and published work, a total of 59 volcanic centers have been identified as active or potentially active, of which 50 have Holocene and 9 Pleistocene activity (Table 4). In terms of geographical distribution, 12 volcanoes are located in Chile, 9 in Argentina, 13 in the Chile-Argentina border, 7 in the Chile-Bolivia border, 2 in Bolivia and 16 in Peru. In terms of types of volcanoes, 34 are stratovolcanoes, 15 are volcanic complex, 3 are volcanic fields, 1 is a pyroclastic cone, 4 are dome complex, 1 is a maar and 1 is a caldera (Supplementary material 1). Among the Holocene volcanoes, 16 volcanoes had at least one eruption in the last 1,000 years. In addition, 36 volcanoes out of the 59 show at least one sign of unrest whereas 3 volcanoes, 1 Pleistocene and 2 Holocene with eruptions older than 1,000 years, show 3 signs of unrest (seismicity, ground deformation and degassing).

4.2 Regional mapping of the CVZA

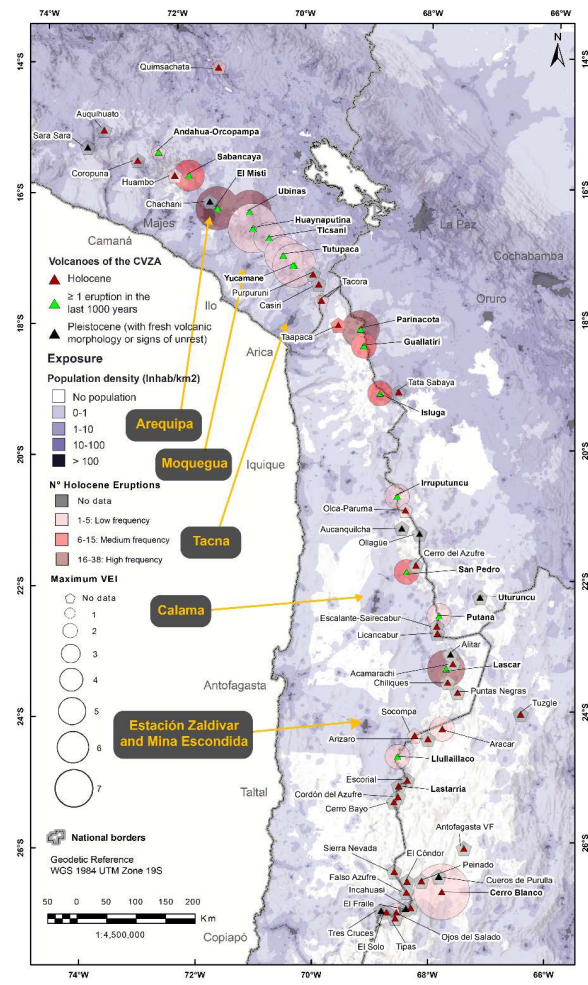

The regional maps resulting from the combination of the total CVZA active and potentially active volcanoes with the density maps of population, transportation and facilities are shown in Fig. 2, 3 and 4, respectively. Five zones with more than 100 inhabitants per km² are identified close to volcanoes showing various eruptive frequencies and VEIs (Fig. 2). The first zone includes the city of Arequipa (Peru), with El Misti and Ubinas volcanoes standing out due to their high eruptive frequency (22 and 26 Holocene eruptions, respectively). The second zone comprises the city of Moquegua (Peru), close to Huaynaputina (maximum VEI of 6), and Ticsani, Tutupaca and Yucamane volcanoes (VEI 2-3, 4 and 5, respectively). The third zone includes the city of Tacna (Peru) close to Tacora, Casiri, Purupuruni and Yucamane volcanoes with the latter last having a maximum VEI of 5. The fourth zone comprises the city of Calama (Chile) close to San Pedro volcano with a medium eruptive frequency (10 Holocene eruptions). The fifth zone corresponds to the mining stations “Estación Zaldivar” and “Mina Escondida”, close to Llullaillaco volcano with low eruptive frequency and VEI (3 Holocene eruptions and VEI 2). Additionally, in the southern zone of the CVZA there is Cerro Blanco volcano (Argentina), whose eruption is among the largest volcanic eruptions of the Holocene globally (VEI 7) (Fernandez-Turiel et al., 2019). Even though Cerro Blanco is not close to inhabited areas with more than 100 inhabitants per km², there are important populated localities within 100 km around the volcano: Antofagasta de la Sierra (730 inhabitants), Palo Blanco (992 inhabitants), Corral Quemado (1200 inhabitants), Punta del Agua (172 inhabitants) and Antinaco (105 inhabitants) (see Supplementary material 2).

Six areas can be identified based on the highest density distribution of transport infrastructure (Fig. 3): First, the cities of Arequipa, Moquegua, and Tacna (Peru), close to the volcanoes Sabancaya, El Misti, Ubinas, Huaynaputina, Ticsani, Tutupaca,

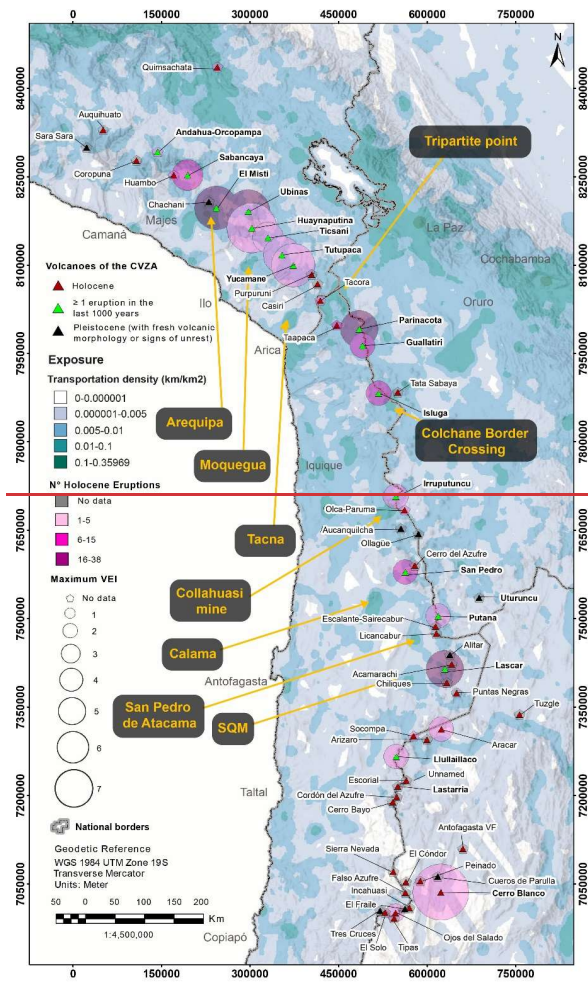

Yucamane, Purupuruni, Casiri and Tacora; ~~second, 2~~) two border crossings, i.e., the triple point (geographical point where the borders of Peru, Bolivia and Chile meet) and Colchane customs post (one of the border ~~erossing~~crossings between Bolivia and Chile), close to the volcanoes Casiri, Tacora and Taapaca (with no confirmed VEI); and Tata Sabaya and Isluga respectively
395 (~~with no information and a medium eruptive frequency (8 Holocene eruptions) and VEI (2), respectively~~); ~~third, 3~~) the Collahuasi mining district (~~a large copper mine, which represents, representing~~ one of the largest copper reserves in Chile and ~~in~~ the world); ~~close to Irruputuncu and Olca-Paruma volcanoes (with, which have a low number of Holocene eruptions and low VEI (2) or not confirmed)~~; ~~fourth, 4~~) Calama city and San Pedro volcano (~~with a medium eruptive frequency (10 Holocene eruptions) and low VEI (2)~~); ~~fifth, 5~~) San Pedro de Atacama town (~~a popular tourist destination in Antofagasta region, (Chile) close to Putana, Escalante-Sairecabur and Licancabur volcanoes (with the formerfirst having 2 Holocene eruptions and VEI 2, and the last two with no information available)~~); and ~~sixth, SQM (6)~~ Sociedad Química y Minera de Chile; ~~(SQM), the world's biggest lithium producer~~) close to Lascar volcano (~~with, which has a high eruptive frequency (37 Holocene eruptions) and maximum VEI (4)~~). Finally, the area with the highest amount of emergency and critical facilities per km² is concentrated in Arequipa city (Peru) close to Sabancaya, El Misti and Ubinas volcanoes (Fig. 4).

425 **4.32 The 2-factor, 3-factor and 4-factor Volcanic Risk Ranking**

The 4619 out of the 59 CVZA active and potentially active volcanoes that had an eruption ~~in~~during the last 1,000 years and ~~the 3 volcanoes showing 3 signs or have significant records~~ of unrest ~~signals~~ were ranked based on the 4 normalized factors of the VRR, i.e., hazard, exposure, vulnerability and resilience (Fig. 55). ~~It is important to first analyse the risk factors separately to better understand what they represent and how they contribute to the overall VRR (Fig. 6)~~. The top five volcanoes showing
430 the highest hazard score are Ubinas (Peru), Lascar (Chile), Sabancaya (Peru), Yucamane (Peru), and Huaynaputina (Peru) (Fig. 5a). The top five volcanoes with the highest exposure score are El Misti (Peru), Ticsani (Peru), Yucamane (Peru), Ubinas (Peru), and Andahua-Orcopampa (Peru) (Fig. 5b). The volcanoes associated with the highest vulnerability scores are Andahua-Orcopampa (Peru), Guallatiri (Chile), Tutupaca (Peru), Ticsani (Peru) and Lastarria (Chile-Argentina) (Fig. 5c). Finally, the
435 top five volcanoes with the highest resilience scores are El Misti (Peru), Ubinas (Peru), Lascar (Chile), Sabancaya (Peru) and Isluga (Chile) (Fig. 5d).

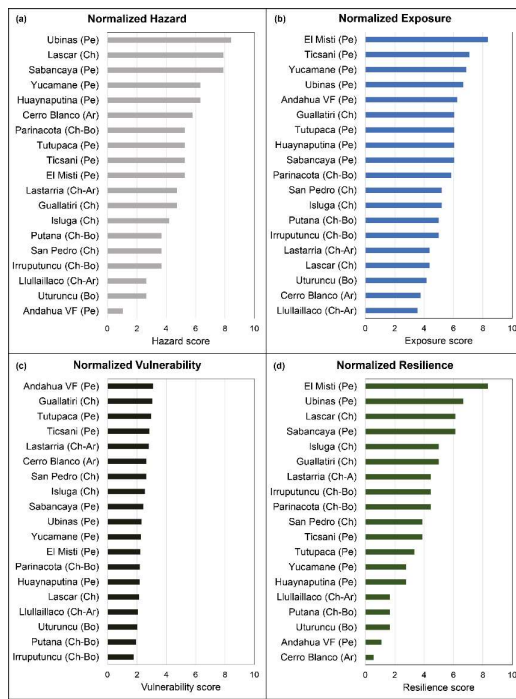

Figure 5: Factors of the volcanic risk ranking analyzed separately. (a) hazard scoring; (b) exposure scoring; (c) vulnerability scoring; and (d) resilience scoring.

When VRR factors are combined, the top five volcanoes with the highest VRR(-0) scores (i.e., hazard and exposure) are Ubinas, Sabancaya, El Misti, Yucamane, and Huaynaputina (Peru) (Fig. 6a); the volcanoes with the 5 highest VRR(-1) scores (i.e., hazard, exposure, vulnerability) are shown by Ubinas, Sabancaya, Ticsani, Yucamane, and El Misti (Peru) (Fig. 6b); while the top five volcanoes with the highest VRR(-2) scores (i.e., hazard, exposure, vulnerability and resilience) are Cerro Blanco (Argentina), Yucamane, Huaynaputina, Tutupaca, and Ticsani (Peru) (Fig. 6c).

450 **Figure 6:** (a) The 2-factor, (VRR-0), (b) 3-factor, (VRR-1), and (c) 4-factor volcanic risk ranking (VRR-2) applied to the 19 CVZA selected volcanoes.

5 Discussion

5.1 Identification of active and potentially active volcanoes

455 Various nomenclatures have been proposed to describe the state of a volcano (e.g., Szakács, 1994; Atiker et al., 2015) and, consequently, when ranking volcanoes of a specific area, the total number of active volcanoes and resulting top-ranked can vary depending on the criterion used (e.g., historical records, geochronological data, recognition of fresh deposits, signals of

unrest). According to Szakács (1994) "active volcano" and "extinct volcano" are mutually exclusive terms. Active volcanoes could be subdivided into "erupting" and "dormant" types based on their current state of activity, while extinct volcanoes could be classified as "young" or "old" using convenient criteria such as the extent of erosion or geochronological age. The term "potentially active" is reserved for those fresh-looking volcanoes lacking both documented eruptions and reliable dating; therefore "potentially active" volcanoes could be "active-dormant" or "extinct-young" volcanoes as more information becomes available (Szakács, 1994). A more recent and restrictive criterion for classification was proposed by Auker et al. (2015). Taking AD 1900 as base year, Auker et al. (2015) defined four frequency classes: active, semi-active, semi-dormant, and fully dormant taking into consideration the period of the last eruption(s) and the unrest. As an example, applying this framework to Chile results in 23 active volcanoes. In contrast, the most recent version of the official Chilean catalog considers 87 volcanoes (Ranking de riesgo específico para volcanes activos de Chile 2023) following the assumption that a volcano is considered geologically active when it has had at least one eruption in the last 11,700 years, i.e., the Holocene period according to Walker et al. (2018), or when, in absence of data of past eruptions in that period, it presents visible signs of current activity such as degassing, seismicity or ground deformation (modified from Simkin and Siebert, 1994; Ewert et al., 2005; Ewert, 2007; Lara et al., 2011). Lara et al. (2021) noticed that the uncertainty on the number of CVZA active volcanoes relies mostly on the lack of geochronological data and/or preserved historical records, in part due to arid erosive conditions, which preclude the morphological distinction between Pleistocene and Holocene units.

5.1 Since geochronological data or preserved historical records are largely absent in the CVZA, the term "potentially active" has been widely used to account for this lack of data. The first comprehensive studies to count active CVZA volcanoes was Casertano (1963) in Chile and Hantke and Parodi (1966) in Peru. Later, the IAVCEI (1973) and Siebert et al. (2011), compiled a list of all the active volcanoes at a global scale also including the CVZA. However, because of the limited knowledge on CVZA volcanoes, most of recent volcanism signs in the Altiplano-Puna catalogs were detected through the analysis of Landsat Thematic Mapper (TM) and experimental Modular Optoelectronic Multispectral Scanner (MOMS) satellite images to identify moraines and valley glaciers left by the last major ice regression in the Central Andes (i.e., 11,000-yr BP). It helped to recognize: i) heavily glaciated volcanoes with no signs of activity since the last deglaciation. ii) Volcanoes with well-preserved surfaces and wholly formed in postglacial times. iii) Volcanoes with no clear relationships between volcanic and glacial features, which were considered to be potentially active if they had fresh volcanic morphological features (i.e., no signs of glaciation, summit craters and flank lava flows with pristine morphology, and flank lava flows with low albedos since lava flows are brighten with age). Besides field observations supported by conventional air photography to provide ground truth for the TM data (De Silva and Francis, 1991). After an extensive data compilation in collaboration with the Geological Services of Argentina (SEGEMAR), Chile (SERNAGEOMIN), and Peru (INGEMMET), combined with a review of the updated volcanic risk rankings of Argentina, Peru and Chile (i.e., Elisondo and Farias, 2023; Macedo et al., 2016; SERNAGEOMIN, 2023; respectively), we observed a discrepancy between the number of potentially active eruptive centers identified by the "Volcanoes of the Central Andes" (n=73; De Silva and Francis, 1991) and the Global Volcanism Program database (n=67;

490 GVP, 2013). As a consequence, the first step of this study was the identification and compilation of all Holocene volcanoes as well as Pleistocene volcanic centers that show unrest signs and/or fresh volcanic morphological features.

495 Since we considered the geological surveys' criteria, our volcano list does not match neither the list of the "Volcanoes of the Central Andes" nor the Global Volcanism Program (De Silva and Francis, 1991; GVP, 2013; respectively). On the other hand, considering previous versions of the relative volcanic risk rankings of Chile and Argentina (i.e., Elissondo et al., 2016; SERNAGEOMIN, 2020) the number of volcanoes considered in Aguilera et al. (2022), were the same (n= 62), even though with some differences. First, Aguilera et al. (2022) did not consider Quimsachata volcano amongst the Peruvian volcanoes, but it is considered by INGEMMET; secondly, they included Ampato volcano as separate from Sabancaya. In our inventory (Table 4), we consider that Sabancaya is the youngest and most recently active system of the Ampato-Sabancaya Volcanic Complex (Rivera et al., 2016; Macedo et al., 2016), also in agreement with INGEMMET and IGP. We removed Caichinque, Pular-Pajonales, Chason-Purico complex, and Colachi volcanoes as they are no longer considered by SERNAGEOMIN (Ranking de riesgo específico para volcanes activos de Chile 2023), as well as the Unnamed volcano (or volcano Sin Nombre) now considered within the Arizaro volcanic field (Elissondo and Farias, 2023). We included Cueros de Parulla and El Fraile volcanoes as they are now in the relative risk ranking of Argentine and neighboring volcanoes (Elissondo and Farias, 2023), and even if Sierra Nevada and Nevado de Incahuasi volcanoes have been removed from the Chilean ranking, we maintain them in our list as they are still considered in the Argentinean ranking.

5.2 Significance of regional mapping and VRR for the CVZA

Regional maps allow for a spatial representation of the areas with a high potential for volcanic impact based on the identification of volcanoes with the largest eruptions and the highest eruptive frequency, as well as the highest density of elements at risk (e.g., population, transport infrastructure, emergency and critical facilities) (FigFigs. 2-4). In the case of As an example, the transport-density map, for example, it is possible to visualize highlights the areas having a high concentration of rural and urban infrastructure, which could also be potentially impacted with some economic consequences on the country. Such This is the case of the Collahuasi mining district in Chile, that has been developed since 1880 when its systems of high-grade copper and silver veins began to be exploited (<https://www.collahuasi.cl/en/quienes-somos/nuestra-historia/>). Nonetheless, these regional maps do not provide the details at local scale (e.g., the type or quality of transport infrastructure and facilities). The Our regional map of the CVZA could be helpful for stakeholders as provides a first preliminary step to quickly identify target areas that require a more detailed risk analysis., representing a helpful approach for stakeholders. The VRR methodology, on the other hand, provides a more spatially discretized and in-depth relative risk analysis that considers 9 hazard, 9 exposure, 10 vulnerability and 13 resilience parameters (Nieto-Torres et al., 2021 and Guimarães et al., 2021). The analysed elements at risk include population, residential buildings and critical infrastructures exposed within four distance radii (i.e., 5, 10, 30 and 100 km), these surfaces cover the area most susceptible to the impact of the different types of hazards such as tephra fallout, pyroclastic density currents and lahars. In case of volcanic fields and calderas, the exposure is analysed

Formatted: Pattern: Clear (White)

for elements inside the volcanic field and for the same radius but from the field's boundary which is defined by the connection of the outermost volcanic edifices that compose it. Differences in the hierarchy of the volcanoes evaluated are mostly due to population density and the diversity of critical infrastructures considered that ensure more densely populated areas to have higher scores in the threat ranking. The vulnerability factor in VRR-1 differentiates volcanic systems with equal or similar threat, while the resilience factor in VRR-2 help to identify volcanoes with no or few mitigation and response measures. The variability between the various VRR approaches (e.g., equations 1–3) confirm the importance of including hazard, exposure, vulnerability and resilience in an integrative ranking analysis in order to capture the risk complexity and best prioritize risk reduction strategies (Fig. 5, 6). Broad common patterns between the regional maps and the VRR are discussed below.

From a hazard perspective, both the regional maps (Fig. 2-4) and the VRR (Fig. 5a) allow to identify Ubinas (Peru), Lascar (Chile), Huaynaputina (Peru) and Cerro Blanco (Chile) as the most hazardous volcanoes. However, El Misti (Peru) and Parinacota (Chile) occupy only the 40th and 7th position on the hazard factor of the VRR, respectively, even though they have a high eruptive frequency (22 and 38 events during the Holocene). The reason is that overall, the maximum hazard score on the VRR represents the highest intensity of each volcanic process, not only eruptive frequency and maximum VEI as in the regional mapping. On the contrary, Sabancaya and Yucamane (Peru) appear at the 3rd and 4th position on the normalized hazard factor of the VRR but are not highlighted in the regional map since they have a medium to low eruptive frequency (14 and 1 event, respectively); and maximum VEIs (3 and 5, respectively).

It is worth noticing that focusing on the VRR analysis of the last 1,000 years of volcanic activity might exclude potentially impactful volcanoes. We constrained this aspect by integrating into the VRR analysis all the volcanoes presenting 3 signs of unrest (i.e., Uturuncu, Lastarria, and Cerro Blanco).

It is worth noticing that the basis of focusing in the last 1,000 years of volcanic activity for the VRR analysis is in line with the methodology proposed by Nieto-Torres et al. (2021) and applied by Guimaraes et al. (2021). Nieto-Torres et al. (2021) found that the volcanoes associated with the highest risk score for Mexican volcanoes were the same, regardless of the analysed time window of eruption occurrence (i.e., <1 and <10 ka). Additionally, Guimaraes et al. (2021), who first applied this methodology on Latin American volcanoes, found that this criterion considers eruptions that are the best constrained in the eruptive records. The grouping of volcanoes based on the age, most recent eruptions and eruption periodicities has also been previously used to rank volcanoes in a general order of "decreasing concern" (e.g., Bailey et al., 1983) and currently the occurrence of eruptions within the last 1,000 years represents one of the controlling factors in developing strategies to increase resilience (Nieto-Torres et al., 2021). However, focusing on the VRR analysis of the last 1,000 years of volcanic activity might exclude potentially impactful volcanoes. For this reason, we constrained this aspect by also integrating into the VRR analysis all the volcanoes presenting records of three signs of unrest (i.e., Uturuncu, Lastarria, and Cerro Blanco). For a more

comprehensive analysis and to confirm our preliminary results, future works could apply the VRR to all 59 active and potentially active volcanoes.

When hazard and exposure are combined, both approaches regional mapping and VRR highlight Ubinas, El Misti, and Huaynaputina as the volcanoes with the highest potential risk (Fig. 2-4 and 6a). However, Sabancaya and Yucamane appear on the 2nd and 4th positions of the threat score (VRR(-0)) and are not highlighted on the regional mapping. The reason is that the regional map only considers the number of Holocene eruptions and maximum VEI as hazard parameters which, with an overlap on the different layers of elements at risk, whilst the VRR evaluates the interaction of 9 hazard and 9 exposure parameters at different radius from the volcanic vent, which turns into a more exhaustive analysis.

The vulnerability factor, which is not considered for the regional mapping, helps to best distinguish volcanic systems with similar threat (i.e., H×E) but different vulnerabilities (e.g., Irruputuncu and Putana volcanoes (Chile)). In particular, the variety of parameters related to the systemic vulnerability helps to highlight the volcanoes with high exposure and low redundancy and accessibility to infrastructures (e.g., Ticsani volcano (Peru)). Finally, the inclusion of resilience in VRR(2) contributes to highlight those systems with moderate (e.g., Tutupaca, Huaynaputina (Peru), and Cerro Blanco (Argentina)) to high score (e.g., Ticsani and Yucamane (Peru)) in the VRR(1) (Fig. 6), (e.g., Ticsani volcano, Peru). Finally, the inclusion of resilience in VRR-2 contributes to highlight those systems with moderate (e.g., Tutupaca, Huaynaputina, Peru; and Cerro Blanco, Argentina) to high score (e.g., Ticsani and Yucamane, Peru) in the VRR-1 (Fig. 6) but having none or few resilience measures implemented (Fig. 5d) (Guimarães et al., 2021). In fact, while the inclusion of vulnerability only affects a few volcanoes (VRR(-0) versus VRR(-1), Fig. 6a-b), the influence of resilience is quite remarkable for all volcanoes, highlighting those systems with none or few mitigation and response (resilience) measures implemented (i.e., Cerro Blanco (Argentina); Yucamane, Huaynaputina, Tutupaca, and Ticsani (Peru)) (Fig. 6c). As an example, Ubinas (Peru) has the highest normalized score in terms of hazard and medium normalized score in terms of vulnerability, but the second highest normalized score in terms of resilience (see Fig. 5), which explains the 1st position in the VRR(-1) and the 7th position in the VRR(-2) (Fig. 6b-c).

The systems taking the top positions of the VRR(-2) are those either with high hazard, medium-high exposure, and vulnerability values, or few to no mitigation and response measures implemented (e.g., Cerro Blanco (Argentina); Yucamane, Huaynaputina, Tutupaca, and Ticsani (Peru)). Considering the low resilience, Cerro Blanco (Argentina) scores as the riskiest volcano of the CVZA due to its low resilience (Fig. 6c).

5.3 Comparison with existing volcanic rankings

Overall, as different dimensions of vulnerability are closely related to the elements at risk, it is important to rethink land-use planning to not increase or create new risk. To reduce vulnerability, it is advisable to create redundancy (e.g., alternative power infrastructure within 100 km of Cerro Blanco) and accessibility to critical infrastructure (e.g., connections to power, water, telecommunication and emergency facilities within 100 km of Cerro Blanco, Ticsani and Tutupaca volcanoes). In addition,

Formatted: Superscript

590 diversification of economic activities should be promoted, especially within 5-30 km around Cerro Blanco, Tutupaca, Ticsani,
Ubinas and Sabancaya volcanoes. However, priority risk reduction strategies should be put in place or improved in order to
increase resilience. First, volcanic records should be better constrained at target volcanoes in order to compile up-to-date hazard
assessments. Within the top five VRR-1 and VRR-2 high risk volcanoes, only Cerro Blanco has no hazard maps, but it is
important to make sure that the existent ones are up-to-date and available for the entire community. Second, monitoring system
595 should be improved for Tutupaca (basic real time), Huaynaputina and Yucamane (limited) and implemented at Cerro Blanco
(non-existent). Third, efforts should be made to compile risk assessments, that is missing at all these 5 high-risk volcanoes
(Cerro Blanco, Yucamane, Huaynaputina, Tutupaca, and Ticsani). Fourth, educational activities should be promoted to raise
awareness in population living around Ticsani, Yucamane, Huaynaputina, Tutupaca, and Cerro Blanco; and existing ones
should be supported and strengthened around Ubinas, Sabancaya and El Misti. Finally, local authorities might invest in
600 preparedness (e.g., evacuation plans and exercises or simulations for institutions and population), insurance coverage,
engineering mitigation measures and implementation of early warning systems.

5.2 Comparison with existing volcanic rankings

To visualize the different existing volcanic rankings ~~easier~~, we have collected ~~their~~ the threat and risk scores in a comparative diagram shown in Fig. 7. At the time of our investigation, three of the four ~~bordering CVZA~~ countries ~~of the CVZA~~ have already developed a relative volcanic threat ranking (i.e., Peru, Chile and Argentina) based on the methodology proposed by
605 Ewert et al. (1998; 2005), in addition ~~with~~ the study of Guimarães et al. (2021) applying the VRR strategy to Latin American volcanoes with activity recorded in the last 1,000 years. The comparison between these rankings is not straightforward because they are all based on diverse ways of considering the risk factors. Consequently, we can find relative threat and risk scores ranging from 0 to 250 (Fig. 7). In addition, each country evaluates only the volcanoes that concern ~~its~~ their own territory whilst ~~the~~ our VRR strategy, ~~comprising a regional scale~~, considers volcanoes from the four ~~bordering CVZA~~ countries ~~of the CVZA~~.
610 Regardless of the relative scoring, ~~there~~ this difference of approaches is a ~~general trend~~ evidenced in Fig. 7, ~~when by the~~ clustering of volcanoes per country. Colours represent each catalogue, comparing the Peruvian volcanoes in green (Macedo et al., 2016), Chilean and bordering volcanoes in grey (~~Ranking de riesgo específico para volcanes activos de Chile 2023~~)(SERNAGEOMIN, 2023) and Argentinian and bordering volcanoes in yellow (~~Elissondo and Farias, 2023~~) against the VRR results in blue (Guimarães et al., 2021) and red (this study) bars (~~Elissondo and Farias, 2024~~) against the VRR results in
615 ~~blue~~ (Guimarães et al., 2021) and red (this study) bars, that are spread along the latitudes 14-28°S.

Figure 7: Comparison of existing volcanic threat and risk rankings. The CVZA volcanoes are organized by latitude, the volcanic systems in bold highlight the ones analyzed for the VRR in this work. Notice that bars represent threat rankings (i.e., VRR0), circles represent the 3-factor VRR1, and squares the 4-factor VRR2. The threat ranking of INGEMMET (Macedo et al., 2016) in green, SERNAGEOMIN (SERNAGEOMIN, 2023) in grey, SEGEMAR (Elissondo and Farias,

620

20232024) in yellow, the threat and risk rankings of Guimarães et al. (2021) in a scale of bluesblue, and the ones of this work in a scale of redsred.

625 Comparing threat rankings in particular, we can point out that three of the five rankings share the same volcanoes in the top 5, with slight differences in the order (Table 53, Fig. 7). The difference in order for the VRR(-0) of between this study and Guimarães et al. (2021) is related to the current update of available data, or used, and subsequently the eruptive period considered, scoring of some indicators such as the recurrence rate. The difference with Macedo et al. (2016) is the absence of Coropuna volcano (Peru) in the list. Interestingly, Coropuna has a higher exposure than Huaynaputina, but was not considered in the work of Guimarães et al. (2021) nor in this study because it didn't have does not account for eruptions during the last 1,000 years or no current, nor records of all three signs of unrest are monitored. The Chilean and Argentinian threat rankings are not directly comparable since none of these Peruvian their ranking doesn't consider volcanoes are considered for being outside of their territory and regarding there is no existing ranking for Bolivian volcanoes, they have not yet its own ranking.

630 Table 53. Comparison of the top 5 CVZA volcanoes of existing threat rankings, considering hazard and exposure (VRR(-0)). Pe: Peru, Ch: Chile, Bo: Bolivia, Ar: Argentina. Underlined volcanoes highlight the ones repeated appearing in different threat rankings.

	This work VRR(-0)	Guimarães et al. (2021) VRR(-0)	SERNAGEOMIN (2023)	Elissondo and Farias (20232024)	Macedo et al. (2016)
1	<u>Ubinas (Pe)</u>	<u>Ubinas (Pe)</u>	Lascar (Ch)	Cerro Blanco (Ar)	<u>Sabancaya (Pe)</u>
2	<u>Sabancaya (Pe)</u>	<u>El Misti (Pe)</u>	Parinacota (Ch-Bo)	Socompa (Ch-Ar)	<u>Ubinas (Pe)</u>
3	<u>El Misti (Pe)</u>	<u>Yucamane (Pe)</u>	Guallatiri (Ch)	Lastarria (Ch-Ar)	<u>El Misti (Pe)</u>
4	<u>Yucamane (Pe)</u>	<u>Sabancaya (Pe)</u>	San Pedro (Ch)	Tuzgle (Ar)	<u>Coropuna (Pe)</u>
5	<u>Huaynaputina (Pe)</u>	<u>Huaynaputina (Pe)</u>	Isluga (Ch)	Llullaillaco (Ch-Ar)	<u>Yucamane (Pe)</u>

640 When comparing the existing threat rankings without the Peruvian (Table 4), it is interesting to notice that the top first volcano is the same for Guimarães et al. (2021), SENARGEOMIN, (2023) and this work, i.e. Lascar volcano located in Chile. With respect to the Chilean or transboundary volcanoes, the top 3 volcanoes are the same between our ranking and the one of SERNAGEOMIN. Then, the Cerro Blanco volcano, which is the top one Argentinian CVZA volcano, appears at the 5th position in our threat ranking. It was considered in our work due to the fact that it has shown the three signs of unrest. Except from this volcano, none of the volcanoes listed by Elissondo and Farias (2014) appears in the top five in the other rankings. This demonstrated the influence of the scale of analysis, country versus region.

645 Table 4. Comparison of the top 5 CVZA volcanoes of existing threat rankings, considering hazard and exposure (VRR-0) only for Chilean and Argentinian volcanoes. Ch: Chile, Bo: Bolivia, Ar: Argentina. Underlined volcanoes highlight the ones appearing in different threat rankings.

	This work VRR-0	Guimarães et al. (2021) VRR-0	SERNAGEOMIN (2023)	Elissondo and Farias (2024)
1	<u>Lascar (Ch)</u>	<u>Lascar (Ch)</u>	<u>Lascar (Ch)</u>	Cerro Blanco (Ar)
2	<u>Parinacota (Ch-Bo)</u>	<u>Isluga (Ch)</u>	<u>Parinacota (Ch-Bo)</u>	<u>Socompa (Ch-Ar)</u>
3	<u>Guallatiri (Ch)</u>	<u>Guallatiri (Ch)</u>	<u>Guallatiri (Ch)</u>	<u>Lastarria (Ch-Ar)</u>
4	<u>Isluga (Ch)</u>	<u>Irruputuncu (Ch-Bo)</u>	<u>San Pedro (Ch)</u>	<u>Tuzgle (Ar)</u>
5	<u>Cerro Blanco (Ar)</u>	<u>Putana (Ch-Bo)</u>	<u>Isluga (Ch)</u>	<u>Llullaillaco (Ch-Ar)</u>

650 When accounting for the vulnerability and resilience factors (VRR(-1) and VRR(-2)), only this work and that of Guimarães et al. (2021) can be compared (Table 65, Fig. 7). When hazard, exposure and vulnerability are combined, both approaches highlight Ubinas, Sabancaya, El Misti and Yucamane within the top five VRR(-1) volcanoes. However, Ticsani appears in the 3rd position of this work and the 7th position of Guimarães et al. (2021), whilst Tutupaca is in the 5th position of Guimarães et al. (2021) and the 6th position of this work. Both volcanoes have the same hazard scores in both studies, however, Ticsani has a higher exposure score, even if the vulnerability is lower than Tutupaca, leading to a higher overall rank in the VRR(-1) produced in this work. The reasons for this are i) a higher population density within the 10, 30 and 100 km; ii) telecommunications score, not considered in Guimarães et al. (2021); and iii) the multiple economic activity source within 100 km for both volcanoes that have been updated with respect to Guimarães et al. (2021).

660 **Table 65. Comparison of the top 5 CVZA volcanoes of existing risk rankings, considering hazard, exposure, vulnerability (VRR(-1)) and resilience (VRR(-2)).** Pe: Peru, Ch: Chile, Bo: Bolivia, Ar: Argentina. Underlined volcanoes highlight the ones repeated in both ranking strategies.

	This work VRR(-1)	Guimarães et al. (2021) VRR(-1)	This work VRR(-2)	Guimarães et al. (2021) VRR(-2)
1	<u>Ubinas (Pe)</u>	<u>Ubinas (Pe)</u>	Cerro Blanco (Ar)	Putana (Ch-Bo)
2	<u>Sabancaya (Pe)</u>	<u>El Misti (Pe)</u>	<u>Yucamane (Pe)</u>	Llullailaco (Ch-Ar)
3	Ticsani (Pe)	<u>Yucamane (Pe)</u>	<u>Huaynaputina (Pe)</u>	<u>Huaynaputina (Pe)</u>
4	<u>Yucamane (Pe)</u>	<u>Sabancaya (Pe)</u>	<u>Tutupaca (Pe)</u>	<u>Yucamane (Pe)</u>
5	<u>El Misti (Pe)</u>	Tutupaca (Pe)	Ticsani (Pe)	<u>Tutupaca (Pe)</u>

665 The major differences occur when considering resilience (VRR(-2) in Table 6 Tables 4, 5 and Fig. 7). Both studies share 3 volcanoes, Yucamane, Huaynaputina and Tutupaca, although in different order. However, Cerro Blanco and Ticsani appear in the 1st and 5th position of our VRR(-2), respectively, whilst Putana and Llullailaco are in the 1st and 2nd position of Guimarães et al., (2021) but only in the 6th and 17th positions of our VRR(-2). There are significant differences in all parameters when scoring these volcanoes in both studies due to a better knowledge of the CVZA volcanoes as well as the available vulnerability and resilience data. Few examples are discussed below.

670 With a VEI of 7, Cerro Blanco represents an important case for the CVZA since its last eruption is one of the largest eruptions worldwide (Fernandez-Turiel et al., 2019). However, it was not considered by Guimarães et al. (2021) because it didn't have an eruption in the past 1,000 years. It is included in our study because we considered volcanoes showing also 3 signs of unrest. From the regional map analysis, we also found that there are important localities within 100 km radius, such as Antofagasta de la Sierra or Corral Quemado (with 730 and 1200 inhabitants per locality, respectively).

675 With a VEI of 7, Cerro Blanco represents an important case for the CVZA since its last caldera eruption is one of the largest eruptions worldwide (Fernandez-Turiel et al., 2019). Whilst it was not considered by Guimarães et al. (2021), not having an eruption in the past 1,000 years, we account for the presence of unrest signs, in agreement with SERNAGEOMIN criteria.

680 From the regional map analysis, we also found that there are important localities within 100 km radius around Cerro Blanco, such as Antofagasta de la Sierra or Corral Quemado (with 730 and 1200 inhabitants, respectively).

685 On the other hand, Putana has the same hazard score, but higher exposure, lower vulnerability and higher resilience scores leading to a lower overall VRR(-2) in this work with respect to Guimarães et al. (2021). Regarding Lullaillaco volcano, it has a lower hazard and vulnerability scores and higher exposure and resilience scores, leading to a lower overall VRR(-2) in our work with respect in contrast to Guimarães et al. (2021). The biggest differences for these two volcanoes are found in the vulnerability factor, mainly due to scoring given by the typology of buildings, its proximity to the Argentina-Chile border, the lack of redundancy of power and telecommunication infrastructures and the multiple economic activities within 30 km radius. In addition, according to our updated information, there are existing hazard maps for Putana volcano (Amigo et al., 2012) increasing its resilience score with respect to Guimarães et al. (2021).

690 **5.43 Data limitations**

It is important to notice the dynamic dimension of all risk factors and emphasize that the parameters of the rankings can be easily updated when new information becomes available, consequently modifying the final score (e.g., Guimarães et al. (-, 2021) versus this work). This is particularly true for the CVZA given the large uncertainties associated with this volcanic zone.

Factor scoring highly depends on the availability, quality and accuracy of data, for either regional mapping or VRR analysis.

695 The complexity and diversity of volcanic hazards and their impacts can exacerbate existing cross-border differences with respect to hazard information, elements at risk, vulnerability, scientific resources, disaster management, mitigation capacity, and public awareness. These differences affect the development of research, sharing of data, accessibility to the information, expertise and resources, and, consequently, the availability and analysis of data (Donovan and Oppenheimer, 2019). Therefore, one of the main challenges for this study was the accessibility to the same level of data and heterogeneity of available datasets across countries, in terms of format, typology (e.g., different names for building types), spatial and temporal scales. As previous works, Therefore, one of the main challenges for this study was the accessibility to the same level of precision and heterogeneity of available datasets across countries, in terms of format, taxonomy (e.g., different names for building types or roads), spatial and temporal resolutions. As previous works (e.g., Guimarães et al., 2021), we also recognize the limitations of the GVP database especially in relation to the eruptive history. For example, after theirthe last update, San Pedro volcano is now listed as Pleistocene (GVP, 2023) San Pedro volcano now is listed as Pleistocene, whilst according with previous information it was(GVP, 2023b), being catalogued previously as Holocene (GVP, 2013), with 10 eruptive events and maximum VEI 2, also in agreement with SERNAGEOMIN. In the case of Parinacota volcano, the number of eruptions is also disagree not consistent, i.e., 6 according to the GVP, (2023), and at least 38 after the updated hazard map of Parinacota recently published by SERNAGEOMIN (Bertin et al., 2022b). Another case is Yucamane volcano, for which the GVP list(2023) lists its last eruption as 1320 BCE, which would leave this volcano out of our VRR but according to INGEMMET its last eruption was 1787 CE

700

710

(Macedo et al., 2016). -Additionally, the ~~time of remote acquisition of up-to-dateness~~ data, in particular for the elements at risk and their vulnerability, is ~~quite highly variable and that affects,~~ influencing the accuracy of the analysis.

Formatted: Pattern: Clear

6 Conclusions

Regional mapping and volcanic risk rankings represent an important tool to identify volcanoes requiring a prioritization of strategies and efforts in volcanic risk reduction. However, the final results strongly depend on the assumptions of the selected VRR methodology and on the availability of data. The selection of volcanoes to evaluate can also vary depending on the objective of the study. Our analysis shows that the most comprehensive list of volcanoes of the CVZA currently comprises a total of 59 active and potentially active volcanic ~~centers-~~centres. However, this number could change in the future if additional information on the various volcanoes become available.

The regional maps compiled for a general visualization of hazard and ~~exposure~~-elements at risk for the 59 volcanoes show that:

- ~~El Misti, Ubinas, Huaynaputina, Parinaeota, Lascar~~ and Cerro Blanco are the volcanoes with the highest eruption magnitude (VEI 6, ~~Huaynaputina; and~~ VEI 7, ~~Cerro Blanco~~) ~~or~~respectively) and the volcanoes with the highest eruption frequency are El Misti (22, ~~El Misti;~~), Ubinas (26, ~~Ubinas;~~), Parinacota (38, ~~Parinaeota;~~) and Lascar (37, ~~Lascar~~).
- Arequipa, Moquegua, and Tacna (Peru), Calama and the mining stations “Estación Zaldivar” and “Mina Escondida” (Chile) are associated with the highest population density ~~of people~~ per km².
- Arequipa, Moquegua, and Tacna cities (Peru), the tripartite point and Colchane customs post (between Peru-Bolivia-Chile and Bolivia-Chile, respectively), and the Collahuasi mining district, Calama city, San Pedro de Atacama town, and SQM (Chile) are associated with the highest density of transport infrastructure per km².
- Arequipa (Peru) is associated with the highest density of facilities per km².

The most threatening volcanoes according to our regional mapping are El Misti and Ubinas, as they are the closest to Arequipa city (Peru), which represents the highest densely populated area, also associated with the highest density of transport infrastructure and facilities per km².

While the regional map provides a ~~fast~~ visual assessment of potential volcanic impact at regional scale, the VRR provides a more comprehensive regional analysis by integrating ~~various~~4 different risk factors. ~~Moreover, integrating all~~In this study, the VRR was focused on the 19 active or potentially active volcanoes presenting 3 signs of unrest allowed the identification of Cerro Blanco, which otherwise would have gone unnoticed in our VRR analysis-based volcanoes having a volcanic activity that

had eruption in the last 1,000 years, or show significant signs of unrest. Results help identifying the riskiesthighest risk volcanoes and those that need to be prioritized in terms of implementing risk reduction strategies. In particular:

- The 3-factor-VRR (Eq.1), which considers hazard and exposure, highlights Ubinas, Sabancaya, El Misti, Yucamane and Huaynaputina as the most threatening volcanoes.
- 745 • The VRR (Eq.2), which considers hazard, exposure, and vulnerability, highlights Ubinas, Sabancaya, Ticsani, Yucamane, and El Misti as the riskiest volcanoes, while Cerro Blanco, Yucamane, Huaynaputina, Tutupaca, and Ticsani represent the riskiesthighest-risk volcanoes when,
- The VRR-2, which also includes resilience parameters, identifies Cerro Blanco, Yucamane, Huaynaputina, Tutupaca, and Ticsani as the 4-factor-VRR (VRR (2), Eq.3) is appliedhighest-risk volcanoes.
- 750 • AsGiven that volcanic hazard and exposure are difficult to modify and reduce, the implementation of risk mitigation measures shouldreduction strategies might focus on reducing vulnerability and increasing resilience, which are highlighted by results of VRR-1 and VRR-2.

• We encourage the use of volcanic risk rankings to characterize volcanic systems and support risk reduction strategies at regional scale, which is especially for Cerro Blanco, Yucamane, Huaynaputina, Tutupaca, and Ticsani volcanoes, valuable in case of cross-border volcanoes. In fact, risk rankings are often carried out at national level, neglecting the complexity of crisis management in case of cross-border eruptions. In the case of the CVZA, most volcanoes are located within less than 25 km from an international border and at least 20 of them share borders, which could result in challenging crisis managements and complex impact patterns. With the hope that our work promotes cooperation between CVZA countries to increase resilience through the co-production of hazard and risk maps, the development of coordinated emergency plans and co-creation of protocols to manage potential impacts, we recommend that further studies are carried out at different scales and this regional VRR could be continuously updated as new information becomes available.

7 Competing interests

The authors declare that they have no conflict of interest.

8 Author Contributions

765 MPRH carried out the compilation of hazard and resilience parameters with the contribution of ME, SG, RA, and GP. LSDM carried out the compilation of exposure and vulnerability parameters with the contribution of LD and CF. MPRH, LSDM and LF carried out the Volcanic Risk Ranking. MPRH and LSDM carried out the regional mapping and drafted the first draft of the manuscript with the contribution of LD, CF, SB, and CB. All authors contributed to the finalization of the manuscript.
