

# Earthquake insurance in Iran: Solvency of local insurers in light of the current market practice

Mohsen GHAFORY-ASHTIANY<sup>1</sup> and Hooman MOTAMED<sup>2</sup>

## Abstract:

Owing to its geographical positioning within one of the most seismically active zones globally, Iran has experienced numerous historically impactful earthquakes. To finance a part of these losses and reconstruction expenses, earthquake insurance has been offered as a rider of fire insurance policy by the Iranian insurers. This mechanism, if well operated, can substantially contribute to disaster risk management. On the other hand, if the pricing and management of catastrophe risk lack a sound, risk modeling-based practice, it might add to the problems and act to the detriment of disaster risk management. In this paper, we first compare the current earthquake insurance pricing and risk management in the Iranian insurance industry with a state-of-the-art insurance regulation in the European Union (Solvency II). Then, we examine the consequence of following each approach in terms of business profitability and viability by conducting a numerical analysis on a hypothetical portfolio of property risks in Iran. In so doing, a seismic risk model has been developed by adopting EMME hazard model and a peer-reviewed vulnerability model, and by developing an exposure model for residential dwellings in Iran. The results suggest that modeled earthquake premium rates are about 5 times larger than the rates currently used in the market. Furthermore, a comparison between solvency capitals calculated following the methods specified by the European Solvency II and the Iranian Directive 69 indicates a visible underestimation of the earthquake solvency capital by the Iranian insurers. It seems that maintaining the current insurance pricing and risk management practice in Iran will probably lead to a substantial accumulation of earthquake risk for domestic firms and eventually endanger the solvency of these companies in the event of large-scale earthquake losses in future.

Keywords: Iran earthquake risk, probabilistic event-based modeling, Insurance pricing, Insurance regulatory, Solvency

30 1 Introduction

31 Being positioned in one of the most seismically active regions in the world, Iran has witnessed many devastating  
32 earthquakes through history, such as the 1978 M7.4 Tabas (USD 11 mn), the 1990 M7.4 Manjil–Rudbar (USD 2.8 bn),  
33 the 2003 M6.6 Bam (USD 1.5 bn), and most recently the 2016 M7.3 Sar-e Pol-e Zahab (USD 5 bn) (Ibrion, et al., 2015;  
34 Maghsoudi & Moshtari, 2020). Although almost all these events occurred in rural areas or small-size cities with less  
35 than 100,000 of inhabitants, the resulting socio-economic consequences have been substantial. If a similar  
36 magnitude earthquake struck a major Iranian city with millions of populations, the volume of physical and human  
37 losses would be much higher.

38 To compensate a part of earthquake losses and facilitate the process of reconstructions, Iranian insurance firms offer  
39 earthquake insurance as a rider of fire insurance policy. However, despite the common practice in the global  
40 insurance market, almost none of the domestic insurers use catastrophe risk models to quantify seismic risk for  
41 pricing policies, purchasing reinsurance, and managing accumulated risks. Instead, old-fashion and seemingly  
42 underestimating pricing tables are still utilised nationally to determine earthquake insurance policies based on main  
43 construction materials and geographical location of insured buildings. This pricing approach is likely to result in  
44 insurance companies collecting insufficient premiums to cover future catastrophe losses. In a similar way, on the  
45 regulatory side, the solvency capital for catastrophe properties is not risk-based and is determined according to the  
46 amount of premium collected (which seem to be not commensurate to risk) and history of company's losses (which  
47 does not reflect long-return period events risks like earthquakes). To date, due to the low penetration rate of  
48 insurance in Iran, about 1.8% in 2022, catastrophe risks assumed by Iranian insurance companies are not significant,  
49 implying that even in the event of medium to large natural catastrophes, the insurance losses usually are  
50 reimbursable by the insurers. With the expected Iran Building Catastrophe Insurance Pool (IBCIP) starting to operate  
51 soon, all residential buildings will be covered under a national policy. As such, there will be likely considerable  
52 business opportunities for domestic insurers to extend their catastrophe property portfolio to provide  
53 supplementary coverage to the primary protection which IBCIP offers. These new business opportunities, although  
54 financially attractive, can dramatically expose Iranian insurance and reinsurance companies to natural hazards risk.  
55 In other words, in the event of major catastrophe events, such as earthquakes in urban cities or widespread flooding,  
56 which are likely in the Iranian geography, many local insurers can quickly become insolvent. These said, it is essential  
57 to examine the of sufficiency of the current insurance rates and the effectiveness of the solvency capital  
58 requirements mandated by Central Insurance of Iran (CII) to cover future catastrophe losses to happen in Iran.

59 In so doing, two parallel approaches have been followed. First, a probabilistic event-based earthquake risk model  
60 was developed which helps calculate risk-based pricing framework for earthquake insurance policies. The model  
61 entails components of a standard catastrophe risk model, namely exposure, hazard, and vulnerability which are  
62 separately adopted, tailored, or developed based on the state-of-the-art methodologies and up-to-date data. These  
63 components are convolved using GEM's OpenQuake as a probabilistic event-based risk assessment platform to  
64 generate risk output such as Average Annual Loss (AAL) and loss Exceedance Probability (EP). In addition, a similar  
65 risk-based methodology to what employed by the European insurance solvency regime, Solvency II, was adopted to  
66 create a standard formula for determining solvency capital for given earthquake risk portfolios. A hypothetical  
67 portfolio of earthquake risks was assumed to compare the factor-based solvency capital (as mandated by CII) with a  
68 risk modeling-based one (as determined following Solvency II methodology) to examine the sufficiency of the current  
69 earthquake rates and solvency capital. Further, the profitability of the underwriting and the likelihood of solvency is  
70 benchmarked using the values generated using the risk-based pricing method and the standard formula of solvency  
71 capital.

72 This paper comprises six sections. First, a background on insurance solvency with a focus on the European Solvency  
73 II and its proposed method for calculating risk-based solvency capital earthquake is provided in Section 2. Then,  
74 Section 3 describes the evolution of earthquake risk models in Iran. Section 3 provides information on the  
75 methodology and data adopted or developed to calculate risk parameters such as AAL and EP (99.5% percentile) and  
76 estimate risk-based solvency capital for a portfolio of risks with earthquake coverage. Numerical results of the  
77 proposed methodology are outlined in Section 4 where the solvency capital of a hypothetical portfolio of risks under  
78 earthquake policy is calculated using the current factor-based and the proposed risk-based methods. A discussion  
79 on the differences between the two methods and possible consequences on the viability of Iranian insurers is given  
80 in Section 5. And finally, Section 6 concludes the process and its findings. A reference list is also provided at the end  
81 of the article.

82 The initial ideas for this research topic emerged during meetings with managers from the Central Insurance of Iran,  
83 the country's insurance regulator. These discussions focused on the necessity of using catastrophe modeling in the  
84 industry. The research process then continued with presentations to insurance executives, sharing the challenges  
85 and potential solutions identified. This represents the final stage of this activity, with the aim of disseminating the  
86 findings at both the regional and international level.

## 87 2 Natural Catastrophe Insurance Regulations in the European Union (EU) and Iran

88 The significance of natural catastrophes and their impact on the viability of insurance firms has received increasing  
89 attention over time, and the occurrence of major catastrophic events such as Hurricane Andrew (1992), the  
90 Northridge Earthquake (1994), Hurricane Katrina (2005), the 2011 Great East Japan Earthquake and Tsunami has  
91 highlighted the issue. Catastrophe losses endanger the solvency of small and medium reinsurance firms and  
92 consume the accumulated provisions of well-capitalised reinsurers (Anderson, 2002). While, to many, the term  
93 catastrophe is closely associated with natural hazards (e.g., earthquake, flood and windstorm), it can also be used  
94 to address intensive damages from human-made events (Lawson, et al., 2001). Catastrophe risks have different  
95 characteristics compared to non-catastrophe losses. They are highly dependent and occur so rarely that historical  
96 claims data could not be efficiently utilised to predict future losses. As a result, the insurance industry has evolved  
97 to prepare for the consequences imposed by disasters by developing risk management rules and regulations. This  
98 section provides a brief history of the regulations regarding the insurance solvency capital as a risk management  
99 measure in the insurance industry, focusing on the European Solvency II regime and the solvency regulations set by  
100 the Central Insurance of Iran (CII) as the national insurance regulator. In addition, technical aspects of calculating  
101 the Solvency Capital Requirement (SCR) in the two abovementioned regulatory systems are described with brevity.

### 102 2.1 European Insurance Solvency Regulation

103 In 2004, Thorburn has provided a history of the difficult times that catastrophic losses created for the insurance  
104 industry and the countries' response to these challenges in the form of developing insurance regulatory institutions  
105 and adopting solvency mandates as an effective measure to manage catastrophe risks to which insurers are exposed  
106 (Thorburn, 2004).

107 In general, insurance supervision aims to protect policyholders' interests by ensuring a sound financial operation  
108 and proper management in the insurance business. Therefore, effective regulations must be established to evaluate  
109 insurers' liabilities adequately and determine provisions to cover these commitments. It is also necessary to consider  
110 an extra layer of protection in the form of capital margin to respond to unexpected financial shocks, e.g., catastrophic  
111 losses. That is why solvency supervision regulations were established and improved over time.

112 Catastrophic losses, both natural and man-made, have resulted in higher claims provisions, reduced capital power,  
113 reduced profitability, and in some cases, made insurance firms insolvent. Remarkable examples of such bankruptcies  
114 are the 1906 San Francisco earthquake with 12 insurance companies declared insolvent, the 1992 Hurricane Andrew  
115 with 9 firms being bankrupt, and the 2011 Christchurch earthquakes that resulted in the ruin of 2 insurance  
116 companies (Kelly & Stodolak, 2013).

117 The first steps in harmonising Europe-wide insurance supervision were taken by the approval of the first non-life  
118 and life insurance<sup>1</sup> Directives in the 1970s (First Council Directive, 1973; First Council Directive, 1979). These  
119 directives required the European Member States to comply with harmonised solvency capital requirements. The  
120 Directives were later revised by adding second and third amendments in 1982 and 1992 (Second Council Directive,  
121 1988; Council Directive, 1990; Directive, 1992; Council Directive, 1992). The entirety of these regulations, which were  
122 later named Solvency 0 by (Sandström, 2019), underwent a comparative examination in the 1990s, showing that  
123 they were not sufficiently taking into account the full spectrum of risks that insurance companies were exposed to.  
124 As such, new directives (known as Solvency I) were again introduced to both life and non-life insurance in 2002 to  
125 fortify the stance of insurers in the event of catastrophic losses (Directive, 2002; Directive, 2002a). Both Solvency 0  
126 and Solvency I regulations followed a similar approach in determining the Solvency Capital Margin, which was mainly  
127 based on factoring gross earned premium and gross incurred claims (Sandström, 2019). However, this was only a  
128 transitional remedy to incorporate a risk-based approach in the insurance solvency capital requirement regulations,  
129 as Solvency I was still inefficient in terms of asset and liability valuation and capital allocation (Rae, et al., 2018). A  
130 drastic reform to solvency regulation was introduced about one decade later as the Solvency II Framework.

131 Influenced by the then-new risk-based banking regulation, Basel-II (Basel Committee on Banking Supervision, 2004),  
132 Solvency II, the latest European insurance supervising regime, replaced Solvency I in 2016. This new regime provides  
133 a more comprehensive risk-based approach for determining solvency requirements for insurance undertakings. The  
134 new regulation also includes a market-based valuation system for assessing companies' assets and liabilities  
135 (Directive, 2009). With a higher degree of confidence, this could potentially reduce the risk of insurance firms being  
136 insolvent. In addition, the Directives contribute to the harmonisation of insurance supervision in the European  
137 market. Solvency II encompasses three pillars, namely Pillar I, Pillar II, and Pillar III. The first pillar focuses on the  
138 quantitative aspects of solvency capital that insurers must hold to cover their risks adequately. The second pillar  
139 addresses the qualitative aspects of solvency regulation, emphasizing risk management and governance, and Pillar  
140 III aims to enhance market discipline by promoting transparency and accountability. Two types of capital  
141 requirements are represented in Pillar I: the Minimum Capital Requirement (MCR) which is the least authorised  
142 capital of insurance companies, and SCR which enables an insurance institution to absorb significant financial shocks,  
143 giving reasonable assurance to policyholders and beneficiaries. Under the underwriting risk category, the institution  
144 can use either a Standard Formula or an Internal Model, each having its pros and cons regarding the level of  
145 sophistication and SCR size. Despite all the promising features and improvements of Solvency II, it has been subject  
146 to much research since its introduction (Rae, et al., 2018; Linder & Ronkainen, 2004; Kousky & Cooke, 2012; Gurenko  
147 & Itigin, 2013; Clarke, et al., 2014; Baione, et al., 2018; Deligiannakis, et al., 2021). These researches mainly focused  
148 on the areas such as economic justification of the then-new solvency regime, different results obtained using the

<sup>1</sup> Life insurance provides coverage for an individual's life and offers fixed health benefits for critical illnesses such as cancer, heart ailments, and more. On the other hand, general insurance or non-life insurance encompasses non-life assets, including houses, vehicles, health, events, travel, and other aspects.

149 Standard Formula of Solvency II and Internal Models, comparison between the implications of Solvency II and  
150 Solvency I, and possible improvements to the new directive.

## 151 2.2 Iranian Insurance Solvency Regulation

152 The Central Insurance of Iran (CII) is the regulator of the Iranian insurance market. As one of its principal duties, CII  
153 approves and enacts decrees and directives through the High Council of Insurance (HCI) to regulate different aspects  
154 of the insurance business in Iran (High Council of Insurance, 2019). Before the approval of the first Directive on the  
155 solvency capital adequacy, CII supervised the operation of Iranian insurance firms by examining monthly reports on  
156 companies' collected premiums and paid claims (Hashemi, et al., 2010). As the pricing system in the Iranian insurance  
157 market was no longer tariff-based then, new regulations needed to be developed and implemented by CII to monitor  
158 the financial solvency of insurance firms. Consequently, Directive 69 was approved and enacted by HCI in 2011,  
159 which required insurance firms to put aside a factor-based solvency capital for four categories of risks: insurance,  
160 market, credit, and liquidity. The Directive also recognized the market value (compared to book value) as the correct  
161 method of valuing own funds in the accounting system. This regulation, which is still in place, represents five classes  
162 of solvency. A company belongs to the first solvency capital level when it keeps a solvency capital equal to or greater  
163 than the Solvency Capital Margin (SCM). Should an insurance company fail to maintain a sufficient solvency margin,  
164 it enters levels 2 to 5 depending on the capital deficit. At level 5 of solvency, CII can officially cancel the business  
165 permission of the insolvent firm. For natural catastrophe policies (fire, engineering, automobile, and life), the SCM  
166 is the greatest of gross earned premium and gross incurred claims, each multiplied by a fixed risk factor (Similar to  
167 Solvency 0). These fixed factors were calculated based on an assessment carried out on the financial statements of  
168 Iranian insurance firms and the financial time series of the Iranian real estate and stock market. The computed  
169 solvency capitals of the named risks are ultimately combined assuming zero correlation between risks to form the  
170 company's SCM. Directive No. 69 was reviewed by (Shahriar, et al., 2016) and a number of improvements regarding  
171 changing the risk metric to Value at Risk (VaR), using a 99% confidence level for calculation SCM, and consideration  
172 of linear correlation for different risks was suggested.

## 173 3 Methodology and Data

174 This section describes the theoretical framework of the quantitative comparison between the methods for  
175 calculating earthquake risk solvency in the Solvency II Directive and Directive 69 of the Iranian insurance regulation.  
176 In so doing, mathematical formulations are detailed in both methodologies, encompassing the selection of risk  
177 metrics, risk factors, and implementation of the risk diversification effect. Then, as a pre-requisite for calculating the  
178 solvency capital, components of a stochastic earthquake risk model for Iran are outlined, covering seismic hazard,  
179 vulnerability, exposure, and financial calculation models. The introduced earthquake risk model estimates the 99.5  
180 loss percentile and Average Annual Loss (AAL) of earthquakes in Iran as input to Solvency II formulas. To feed  
181 Directive 69, the conventional earthquake risk pricing table of the industry is utilised.

182 A hypothetical portfolio of 1500 residential dwellings evenly distributed between three main construction types of  
183 steel, reinforced concrete, and masonry, and across five provincial capital cities of Tehran, Esfahan, Tabriz, Ahvaz,  
184 and Kerman has been considered to compare the earthquake risk solvency charge calculated by each methodology.  
185 The reason for selecting these capital cities is that they are located in various and seismicity zones and contain  
186 different composition of construction types. This allows us to consider the effect of diversification in the comparison  
187 process.

188 3.1 Calculation of earthquake solvency capital

189 3.1.1 Directive 69

190 High Council of Insurance (2011) requires insurance and reinsurance institutions to hold eligible own funds as the  
191 solvency capital using the fixed factors determined for different types of risks, namely underwriting, market, credit,  
192 and liquidity risks. The Directive provides risk factors for miscellaneous lines of business, including catastrophe fire  
193 insurance (non-life) without any distinction between various natural catastrophes in terms of fixed risk factors and  
194 assumes zero correlation between risks in different lines of business and geographies (meaning that losses are  
195 deemed fully independent). According to this directive, to calculate the solvency charge of a property catastrophe  
196 portfolio, first, the products of gross earned premiums and gross incurred claims with their corresponding risk factors  
197 (0.580 and 0.841, respectively) are computed, and then the greatest of these values is considered as the solvency  
198 capital. Since no reliable information on the gross incurred earthquake loss claims were available to us at the time  
199 of writing this paper, we only use the term determined by gross earned premiums. In so doing, average values of  
200 earthquake premium rates of five Iranian insurance firms, which were extracted from a popular Iranian insurance  
201 quotes aggregator website<sup>2</sup> are employed to calculate the premium-based part of the formula for the portfolio.  
202 These rates are still based on a study conducted in 1991 by (Ghafory-Ashtiany, 1991) who determined the relative  
203 riskiness of different construction types in various seismic zones in Iran (please see the original table at Table A1).  
204 Table 1 presents average market earthquake insurance premiums for masonry, concrete, and steel buildings of 10  
205 years of age in five provincial capital cities. It seems the rates provided do not accurately reflect the building class  
206 vulnerabilities and seismic risk profiles of the cities mentioned. An appropriate approach is to leverage catastrophe  
207 risk modeling exercise to determine more reasonable premium rates which is addressed in the following sections of  
208 the paper.

209 It should be noted that we have selected these cities as representatives of different seismic zones in Iran; Tehran  
210 and Tabriz in highly seismic Alborz zone in Northern Iran, Esfahan in low seismicity central areas, Khuzestan in low  
211 seismicity southwestern Iran, and Kerman to medium-high seismic zone of Zagros.

**Table 1: Market earthquake premium rates (in 1000) for different building types in various province capital cities in Iran**

| Province        | County <sup>3</sup> | Capital city | Construction type |       |          |
|-----------------|---------------------|--------------|-------------------|-------|----------|
|                 |                     |              | Masonry           | Steel | Concrete |
| Tehran          | Tehran              | Tehran       | 1.1               | 0.50  | 0.50     |
| East Azarbayjan | Tabriz              | Tabriz       | 1.1               | 0.50  | 0.49     |
| Esfahan         | Esfahan             | Esfahan      | 0.78              | 0.33  | 0.32     |
| Kerman          | Kerman              | Kerman       | 1.1               | 0.37  | 0.36     |
| Khuzestan       | Ahvaz               | Ahvaz        | 0.78              | 0.33  | 0.32     |

212

<sup>2</sup> Azki.com

<sup>3</sup> County or Shahrestan is second-order administrative division of Iran.

213 3.1.2 Solvency II

214 As outlined in Annex IV of Directive 2009/138/EC (2009) and CEIOPS (2010) on the application of the natural  
 215 catastrophe Standardised Scenarios (standard formula), to calculate earthquake charge, the Weighted Total Value  
 216 Insured (WTIV) should be computed at CRESTA<sup>4</sup> level using the Total Insured Value<sup>5</sup> (TIV) for each line of business.  
 217 Eq.1 presents the mathematical formulation of this stage (Directive, 2009; Committee of European Insurance and  
 218 Occupational Pensions Supervisors (CEIOPS), 2010).

$$WTIV_{ZONE} = F_{ZONE} \times TIV_{ZONE} \quad \text{Equation 1}$$

219 Since the 99.5% VaR, as the risk factor, are provided at the country level in CEIOPS (2010), a relativity factor ( $F_{ZONE}$ )  
 220 takes the role of adjusting the national risk factor at subnational (CRESTA) level in the Standardised Scenario. The  
 221 catastrophe capital charge ( $CAT_{peril-ctry}$ ) is then calculated by applying the effect of geographical aggregation of  
 222 WTIVs of different CRESTA zone within the country of interest multiplied by  $Q_{CTRY}$  (1-in-200-year risk factor of  
 223 earthquake at country level). Eq.2 illustrates the calculation of solvency capital required for earthquake risk at the  
 224 country level.

$$CAT_{PERIL-ZONE} = Q_{CTRY} \times \sqrt{[WTIV_{ZONE}]^T [AggMat] [WTIV_{ZONE}]} \quad \text{Equation 2}$$

225 Where  $[WTIV_{ZONE}]$  is the array presentation of WTIV within the country (of interest and  $[WTIV_{ZONE}]^T$  is its  
 226 transposed form.  $[AggMat]$  is basically a correlation matrix determining how different CRESTA zones are correlated  
 227 to each other in terms of experiencing simultaneous earthquake loss and it comprises elements of 1 (fully  
 228 correlated), 0.5 (semi correlated), 0.25 (slightly correlated), and 0 (no correlation). CEIOPS (2010) provides sub-  
 229 country correlation matrices for EEA countries in an excel spreadsheet.

230 To follow the procedure proposed by Solvency II to calculate the catastrophe charge for earthquake risks in Iran, we  
 231 use the output of a stochastic earthquake risk model developed in this study, separately presented in section 3.2.  
 232 This catastrophe model can produce risk results (e.g., AAL or 1-in-200-year loss) at finer administrative levels than  
 233 CRESTA. In accordance with local underwriting and risk management practice in Iran, we use the county-level  
 234 resolution to calculate the solvency capital. Therefore, there is no need to use a relativity factor for TIV at the county  
 235 level since we already have the Q factor for each county. That said, we can rewrite Eq.1 to Eq.3:

$$CAT_{EQ-County} = Q_{County} \times TIV_{County} \quad \text{Equation 3}$$

236 Here, we can directly calculate each county's catastrophe charge for earthquake risk. Following that, we aggregate  
 237 these charges at a province and then country level to determine the total solvency capital for a given portfolio of  
 238 earthquake risks. Eq.4 and Eq.5 exhibit the mathematical form of these calculations.

$$CAT_{PERIL-ZONE} = \sqrt{[WTIV_{ZONE}]^T [AggMat_{Province}] [WTIV_{ZONE}]} \quad \text{Equation 4}$$

---

<sup>4</sup> CRESTA zones are a system used in the insurance industry to evaluate and manage catastrophe risks. CRESTA stands for "Catastrophe Risk Evaluation and Standardizing Target Accumulations." These zones are geographic areas that are defined based on various factors, including seismic activity, weather patterns, and other natural perils.

<sup>5</sup> Total Insured Value (TIV) refers to the total amount of insurance coverage that an individual, organization, or entity has on its assets, properties, or liabilities

$$CAT_{PERIL-ZONE} = \sqrt{[WTIV_{ZONE}]^T [AggMat_{Country}] [WTIV_{ZONE}]} \quad \text{Equation 5}$$

240 The symmetric aggregation matrices for province and country levels are constructed using either 1 (fully correlated),  
 241 0.5 (semi-correlated), 0.25 (slightly correlated), and 0 (non-correlated) members. It is assumed, mainly considering  
 242 distance factor, that each county is fully correlated with itself and semi correlated with its neighbouring counties. In  
 243 the case of provinces, due to the larger size, the neighbouring provinces are assumed to be slightly correlated.

### 244 3.2 Modeling the Earthquake Risk in Iran

245 As a requisite for using a risk-based methodology in calculating the earthquake risk capital charge, for example, the  
 246 described method by Solvency II, it is necessary to have a stochastic catastrophe model for quantifying the required  
 247 percentile of confidence of seismic losses (here, 99.5%) at different locations and for various construction types. This  
 248 subsection explains how we developed an earthquake risk model for Iran utilizing the most reliable methodologies  
 249 and the highest quality of data. The subsection describes the risk model components: the calculation platform  
 250 (OpenQuake), seismic hazard model, residential building exposure model, and vulnerability functions. Because this  
 251 paper's main objective is to compare solvency capital calculation methods, efforts were made to keep the risk model  
 252 development description as brief as possible.

253 The common practice for quantifying natural catastrophe risks in the insurance industry is (event-based) stochastic  
 254 catastrophe modeling. The process incorporates three main components of hazard, exposure, and vulnerability using  
 255 a Monte Carlo simulation method to generate loss results. Loss results are then post-processed to calculate risk  
 256 parameters such as Average Annual Loss (AAL) and loss Exceedance Probability (EP) for specific level of confidence  
 257 which are employed for various underwriting and risk management decisions in the business. The practice of  
 258 modeling seismic risk in Iran is rather in its early stage and a few studies have been conducted on catastrophe  
 259 modeling over the last decade, e.g., (Ghafory-Ashtiany & Nasserassadi, 2012), (Pakdel-Lahiji, et al., 2019), (Motamed,  
 260 et al., 2019), (Shahbazi, et al., 2020), and (Bastami, et al., 2022). In this study, the open-source OpenQuake platform  
 261 developed by the Global Earthquake Model (GEM) foundation was utilised to do the seismic risk modeling, due to  
 262 its recognition in the insurance market and its flexibility in terms of input data and generation of required risk  
 263 parameters.

#### 264 3.2.1 Seismic hazard model

265 After reviewing several available studies on the seismic hazard of Iran (Motamed, et al., 2019; Mirzaei, et al., 1997;  
 266 Tavakoli & Ghafory-Ashtiany, 1999; Yazdani & Kowsari, 2013; Şeşetyan, et al., 2018; Lotfi, et al., 2022; Pagani, et al.,  
 267 2020), the Earthquake Model of Middle East (EMME) (Şeşetyan, et al., 2018) was selected due to the availability of  
 268 its OpenQuake-ready input data and credibility of the study in the earthquake engineering society. The EMME  
 269 seismic model comprises two models for line and area sources, prepared with collaboration of seismologists from  
 270 Iran, Middle East region, and Europe. In this study, only seismogenic sources within Iran and a 300 km beyond its  
 271 borders have been considered. Figure 1 illustrates the delineation of seismogenic zones and active faults used in the  
 272 input seismicity model.

Figure 1: Seismogenic sources of EMME project used in the seismicity model: Area sources (a) and fault sources (b)  
Original maps from (Danciu, et al., 2018)

273

274 In addition, a set of Ground Motion Prediction Model Equations (GMPE) for different seismotectonic characteristics  
 275 in Iran (including active shallow crustal, stable shallow crustal, subduction, and deep seismicity sources), and two  
 276 logic trees for treating epistemic seismic hazard uncertainty were utilized to calculate the ground motion intensity  
 277 parameter (PGA) at exposure locations. Figure 2 exhibits the structure of the GMPE logic tree and the attenuation  
 278 relationships that were employed in the hazard model. The minimum magnitude of 5 was used in the analysis due  
 279 to its impact on building damage and optimizing the computation demand. These are the same settings suggested  
 280 in EMME project, however; we used a more recent version of GMPEs whenever possible.

281

282

Table 2: GMPEs used in the hazard model and their corresponding weights

| Seismotectonic type  | GMPE                   | Weight |
|----------------------|------------------------|--------|
| Active shallow crust | (Akkar & Cagnan, 2010) | 0.20   |
|                      | (Akkar, et al., 2014)  | 0.35   |

|                      |                          |      |
|----------------------|--------------------------|------|
|                      | (Chiou & Youngs, 2008)   | 0.35 |
|                      | (Zhao, et al., 2006)     | 0.10 |
| Stable shallow crust | (Atkinson & Boore, 2006) | 0.40 |
|                      | (Toro, 2002)             | 0.25 |
|                      | (Campbell, 2003)         | 0.35 |
| Subduction interface | (Atkinson & Boore, 2003) | 0.20 |
|                      | (Lin & Lee, 2008)        | 0.20 |
|                      | (Youngs, et al., 1997)   | 0.20 |
|                      | (Zhao, et al., 2006)     | 0.40 |
| Subduction in-slab   | (Atkinson & Boore, 2003) | 0.20 |
|                      | (Lin & Lee, 2008)        | 0.20 |
|                      | (Youngs, et al., 1997)   | 0.20 |
|                      | (Zhao, et al., 2006)     | 0.40 |
| Deep seismicity      | (Lin & Lee, 2008)        | 0.50 |
|                      | (Youngs, et al., 1997)   | 0.50 |

283

284 To convert bed rock ground motion intensity to ground-level PGA, a soil model (shear velocity distribution) based  
 285 on methodology suggested by Allen and Wald (Allen & Wald, 2009) was used. Using the components adopted, an  
 286 event-based probabilistic seismic hazard analysis was carried out using GEM<sup>6</sup>'s OpenQuake engine and 20,000 years  
 287 of seismicity were simulated. Figure 2 illustrates the Peak Ground Acceleration (PGA) distribution on the bedrock  
 288 with an equivalent return period of 475 years in Iran, based on averaging several realizations of PGAs.

---

<sup>6</sup> Global Earthquake Model

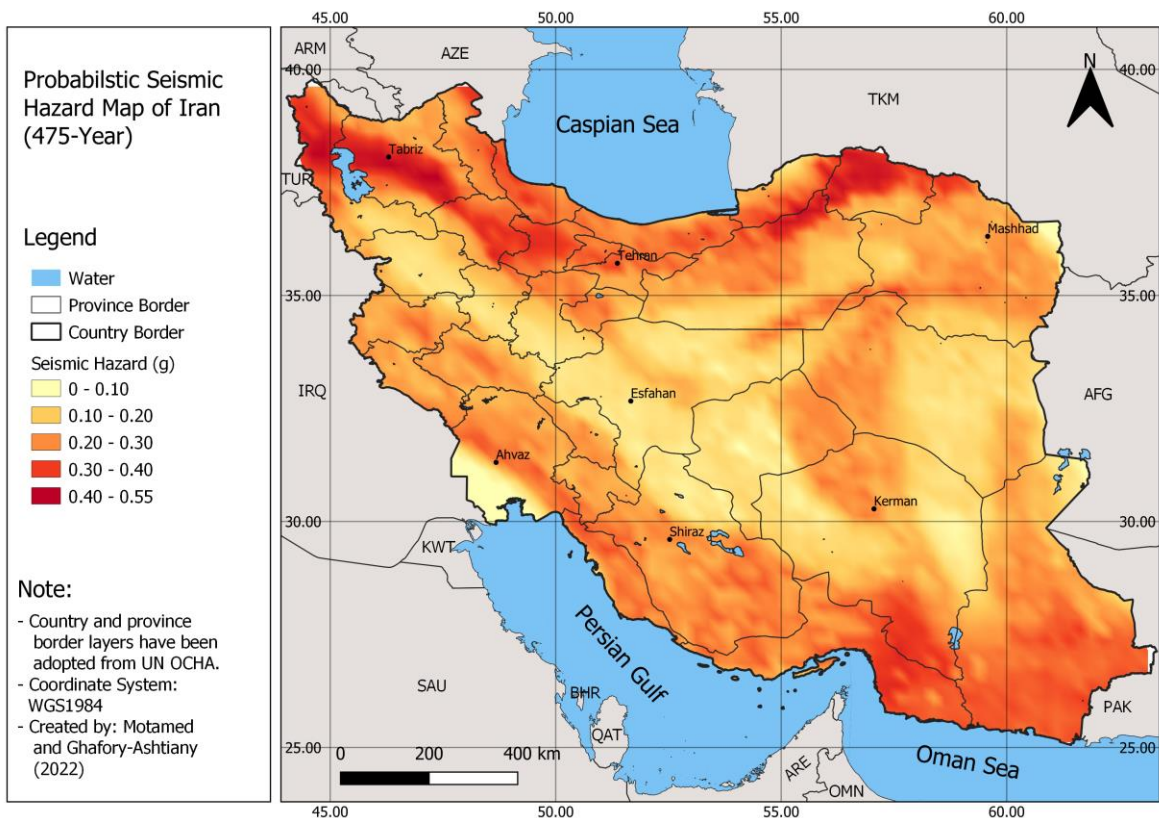

Figure 2: Spatial distribution of hazard parameter (PGA) of 475-year return period

289 As seen in Figure 2, the northern part of the country (Alborz and Koppe-Dagh seismotectonic zones), including the  
 290 cities of Tabriz and Tehran, and south-eastern regions (central Iran and Makran zones) containing the city of Kerman  
 291 show the highest levels of seismic hazard. In the Zagros zone in western-southwestern Iran, the PGA level is lower  
 292 than northern and southeastern parts, but still high. On the flip side, the province of Esfahan in central Iran and  
 293 southwestern parts of Khuzestan in south-western Iran contain zones with the lowest PGA levels. The sharp contrast  
 294 in PGA values in Khuzestan is due to the lack of seismic events and active faults in this region which has been  
 295 smoothed in the Inverse Distance Weighted (IDW) method. Other regions fall between these upper and lower  
 296 seismicity limits.

297 Attention should be paid that this study has been carried out at the national level; therefore, the resolution is coarser  
 298 than more accurate local studies and both distribution and intensity of PGAs might be different to such works. To  
 299 validate the results of the hazard model, we compared our results with some recent seismic hazard analysis studies  
 300 conducted at national or regional levels for Iran over the recent years, including (Lotfi, et al., 2022), (Lloyd's and CAT  
 301 Risk Solutions, 2017), and (Şeşetyan, et al., 2018). Table 3 summarizes the results of seismic hazard analysis (10%  
 302 probability of exceedance in 50 years equal to 475-year) for these studies and the present work.

Table 3: Comparison of the seismic hazard analysis results in this research with other studies

| Study | Min PGA (g) on bedrock | Max PGA (g) on bedrock | Geographic zones with highest PGA |
|-------|------------------------|------------------------|-----------------------------------|
|-------|------------------------|------------------------|-----------------------------------|

|                                       |      |       |                                   |
|---------------------------------------|------|-------|-----------------------------------|
| Lotfi et al (2022)                    | 0.1  | 0.55  | N and SE (very high), W-SW (high) |
| Şeşetyan, et al. (2018)               | 0.1  | 0.5   | N and SE (very high), W-SW (high) |
| Lloyd's and Cat Risk Solutions (2017) | 0.05 | >0.40 | N and W-SW (very high), SE (high) |
| Present study                         | 0.05 | 0.55  | N and SE (very high), W-SW (high) |

303 As seen, there is an acceptable similarity between the range of 475-year PGAs and spatial distribution of it at the  
304 national level.

### 305 3.2.2 Vulnerability model

306 To estimate the damage ratio of exposed assets under a given earthquake scenario with known intensity parameters  
307 (in this study PGA), it is necessary to use vulnerability functions. These are typically functions or curves that relate  
308 various levels of hazard intensity to damage ratio or percentage for specified types of groups of assets (vulnerability  
309 classes). In this study, the vulnerability curves developed by Mansouri and Amini-Hosseini (2013) as one of the  
310 components of the project Earthquake Model of the Middle East (EMME) (Şeşetyan, et al., 2018) were used due to  
311 the credibility of the methodology used (RISK-UE), consistency with building attributes publicly available for Iranian  
312 buildings (please look at the exposure model section), and compatibility with past earthquake losses in Iran). In this  
313 study, 10 building vulnerability classes were defined based on construction material, height of building, and  
314 construction vintage as a proxy for the ductility of the structure to earthquake loads. Table 4 summarizes the  
315 vulnerability classification of Iranian buildings based on their physical attributes.

| Vulnerability class | Material type        | Height category | Construction date | Short description      |
|---------------------|----------------------|-----------------|-------------------|------------------------|
| Adobe               | Adobe                | Low-rise        | All time periods  | High vulnerability     |
| M1                  | Reinforced masonry   | Low-rise        | 1996-2006         | Low vulnerability      |
| M2                  | Unreinforced masonry | Low-rise        | 1996-2006         | High vulnerability     |
| M3                  | Unreinforced masonry | Low-rise        | Before 1976       | High vulnerability     |
| RC3                 | Concrete frame       | Mid-rise        | Before 1976       | High vulnerability     |
| RC2                 | Concrete frame       | Mid-rise        | 1976-1996         | Moderate vulnerability |
| RC1                 | Concrete frame       | Mid-rise        | 1996-2006         | Low vulnerability      |
| S3                  | Steel frame          | Mid-rise        | Before 1976       | High vulnerability     |
| S2                  | Steel frame          | Mid-rise        | 1976-1996         | Moderate vulnerability |
| S1                  | Steel frame          | Mid-rise        | 1996-2006         | Low vulnerability      |

316

317 Since the newest vintage of buildings at the time conducting this study was 2016, we shifted the original vulnerability  
318 (Table 4) by 10 years to pre-1986, 1986 to 2006, and post-2006. This is a valid modification because buildings had  
319 become 10 years older after the publication of the original paper and since then a new version of the Iranian  
320 Standard for Seismic design of buildings had come into force in 2014. These classes and their corresponding  
321 vulnerability curves represent seismic vulnerability of ten building classes of adobe (one class), masonry (three  
322 classes), steel (three classes), and reinforced concrete (three classes). Figure 3 exhibits examples of these curves for  
323 different types of building with medium-quality construction. am, mm, rcm, sm in this figure stand for medium-  
324 quality adobe, masonry, reinforced concrete, and steel buildings.

Figure 3 Vulnerability curves for medium-quality adobe (am), masonry (mm), reinforced concrete (rcm), and steel (sm) buildings (Mansouri & Amini-Hosseini, 2013)

325 As shown in this diagram, adobe is the most vulnerable class of building to earthquakes, while reinforced concrete  
326 and steel buildings offer the highest resistance to seismic loads. Masonry buildings fall between these two ranges.  
327 Also, buildings with older date of construction are considered more vulnerable to seismic forces.

328

### 329 3.2.3 Residential building exposure model

330 The exposure model provides attributes of the buildings at risk, such as physical attributes (material type, year built,  
331 height of the building), their monetary value, and their geographic locations in terms of, for example, geographic  
332 coordinates. The Iranian census data classifies the building materials into three main classes of steel, reinforced  
333 concrete, and masonry. The masonry class is furthered split to Brick & Steel or Stone & Steel, Brick & Wood or Stone  
334 & Wood, Cement Block (all kind of Roofs), All Brick or Brick & Stone, and All Wood. In this study, we only consider

335 residential building because their attributes are collected on a regular basis in the national population and housing  
336 census and reported by the Statistical Centre of Iran (SCI) every 5 years. The date of constructions is expressed in  
337 10-year, 5-year, and 1-year bins depending on the vintage of buildings since 1966. The census data is freely available  
338 at SCI website at county granularity. Due to the fact that the census data has not been updated since 2016, we have  
339 used 2016 datasets to develop the exposure model. Figure 4 illustrates common types of Iranian residential buildings  
340 in the city of Tehran.

341

(a)

(b)

(c)

(d)

Figure 4: Examples of common residential buildings in Tehran: adobe (a), steel (b), reinforced concrete (c), masonry (d)

Photos by Ms. Niloofar Kazemi Asl

342 Until 2011, SCI reported four sets of building attributes, namely building material, construction date, and number  
343 and build area of dwellings split by building types and year built. We used the same vulnerability classes introduced  
344 by (Mansouri & Amini-Hosseini, 2013) as exhibited in Table 3 so that they are consistent with adopted vulnerability

345 curves. Because census data of 2016 lacked the attribute of building vintage, we used the previous census data  
346 (2011) vintage attribute and updated it by making an assumption that if the number of dwellings has decreased  
347 between 2011 and 2016 census in a given county, the reduction would be due to destruction of buildings belonging  
348 to the oldest vintage bin, and if the number increased, that would be because of newly built buildings, thereby  
349 affiliating to the newest vintage bin. This assumption is compatible to the reconstruction trend of buildings and  
350 settlement development in Iran.

351 No national dataset on the number of stories or height of the buildings is available in Iran. As a results, we assumed  
352 a low-rise height class for adobe and masonry buildings and mid-rise class for steel and reinforced concrete buildings  
353 in Iran based on an engineering judgement. An estimate of construction cost of residential buildings can be enquired  
354 from builders in different provinces. The value of existing buildings can also be estimated by depreciating the value  
355 of the newly constructed buildings based on the date of construction or building vintage bins in the vulnerability  
356 model. Based on the research conducted, the average cost of construction per sqm in Iran in 2016 was USD 300.  
357 Using the data on build area and number of dwellings, we estimated the average building surface area of about 100  
358 sqm for Iranian dwellings.

359 After creating the datasets for 10 building types at the county level, we used population data of Landscan (Bright, et  
360 al., 2017) with a 30-arc-second resolution to downscale the county-level building exposure data to a finer resolution  
361 for the loss calculation purpose. To accomplish this, we divide the number of dwellings of each building type by the  
362 total number of populations of the county to compute the number of dwellings per person, then we multiply the  
363 results to the number of populations in each cell to come up with number of dwellings in that cell. The process is  
364 repeated for all types of building for each county. Figure 5 presents the spatial distribution and monetary value of  
365 different building types of residential dwellings in Iran at the county level. Please note that numbers are absolute  
366 value of each building type at the county level.

367

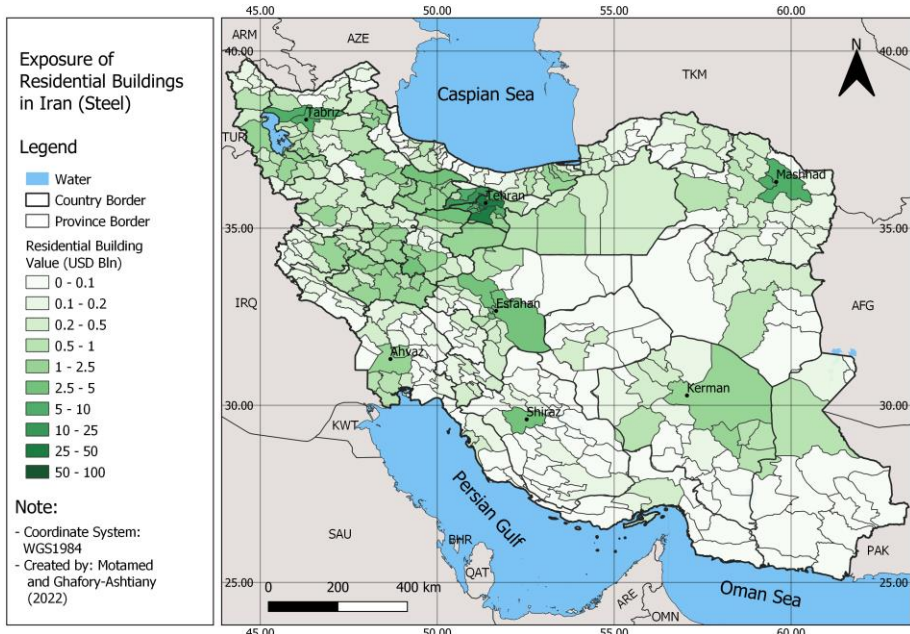

(a)

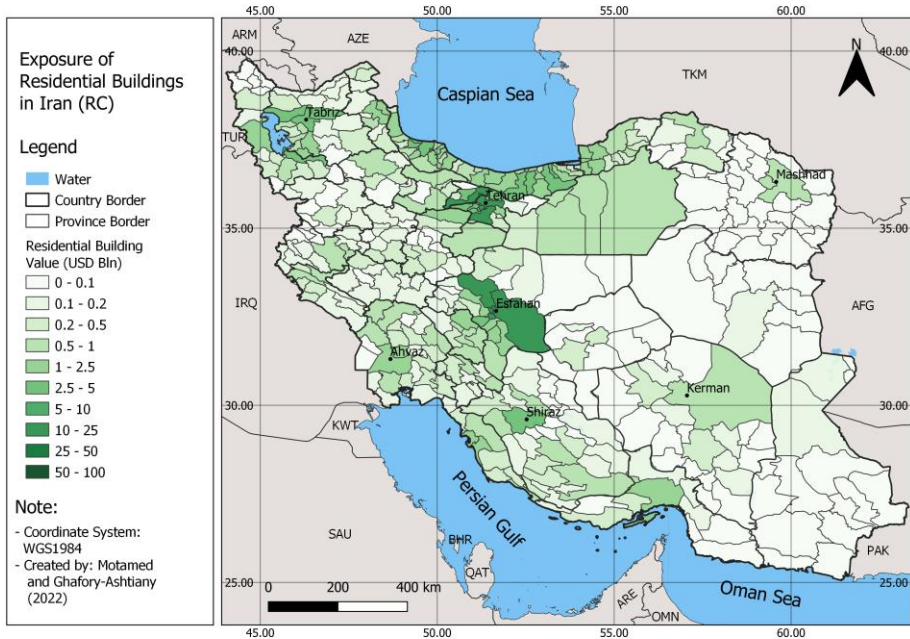

(b)

(c)

(d)

Figure 5: Exposure of residential buildings in Iran, adobe (a), masonry (b), steel (c), and concrete (d)

368 From a holistic point of view, most residential buildings are concentrated around the highly-populated capital cities  
 369 of Tehran, Tabriz, Esfahan, Mashhad and Shiraz which is consistent with results of 2016 housing and population  
 370 census which ranked provinces of Tehran, Esfahan, Razavi Khorasan (including Mashhad city), Fars (including Shiraz),

371 Markazi (containing Arak), Khuzestan (including Ahvaz), and East Azarbayjan (including Tabriz) with largest  
 372 residential built area As observed in map (a), the highest value of county-wise adobe buildings as the most vulnerable  
 373 type is Esfahan (center of Iran), Fars (south), Kerman (east) and Sistan and Baluchestan (southeast). Also, masonry  
 374 buildings, as the second most vulnerable building type, are almost common across the country with a more visible  
 375 presence around the capital cities of Tabriz, Tehran and Mashhad in the north, Esfahan in the center, Shiraz in the  
 376 south, and Ahvaz in southeast (See map 'b'). The two more earthquake resistant building types, namely steel and  
 377 reinforced concrete are more frequent around capital cities of Tehran, Tabriz, followed by Esfahan, Mashhad, and  
 378 Shiraz. According to statistical analyses on the exposure data, about 55% of residential dwellings in 2016 were made  
 379 of modern construction materials such as steel and reinforced concrete, while the remaining 45% belonged to other  
 380 types including masonry and adobe.

381 **4 Numerical Results**

382 After preparing the components of the risk model, an event-based probabilistic approach has been used to assess  
 383 seismic risk of the Iranian residential dwellings. To achieve that, GEM's OpenQuake hazard and risk calculation  
 384 engine was adopted due to its credibility within the earthquake engineering society, its transparency in terms of  
 385 technical documentations, and flexibility in using different approaches in modeling risk. Figure 6 illustrates the  
 386 schema of OpenQuake's probabilistic event-based engine and its input/output structure.

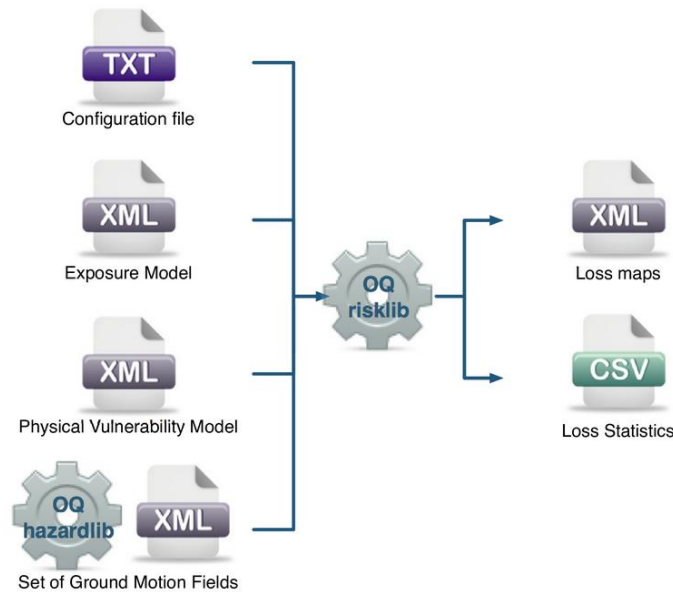

Figure 6: GEM's OpenQuake schema and its input and output components (OpenQuake website<sup>7</sup>)

387

388 As described, the exposure, vulnerability, and hazard models need to be converted to required format before being  
 389 incorporated in the engine. In addition to that, a configuration file that introduces the input data and other analysis  
 390 parameters such as type of analysis (here: probabilistic event-based), number of simulated years (here: 20,000  
 391 years), and types of output, is required to set up the risk analysis. The risk assessment process starts with OpenQuake

<sup>7</sup> <https://docs.openquake.org/oq-engine/manual/latest/risk.html> accessed in 10 December 2023

392 hazard engine generating sampled earthquake events using the hazard model provided. For each seismic event  
393 generated, ground motion field (distribution of PGA on top soil) is calculated using GMPE models and the soil shear  
394 velocity information for all the locations existing in the exposure model within a defined radius around the sampled  
395 epicenter (here 150 km). Then, based on the typology of buildings at each location (a cell of 30-second arc  
396 dimension), relevant vulnerability curves are used to convert PGA value to damage percentage. Further, the damage  
397 percentage is multiplied with replacement value of that type of building to calculate loss. These OpenQuake output  
398 is then post-processed to calculate aggregate loss at different levels, namely county, province, and country. These  
399 values should be normalized to their corresponding exposure values for each building type to compute AAL rates.  
400 The same process is done, this time using EP 99.5% to calculate 1-in-200 EP loss for each building type at  
401 aforementioned aggregate levels which are adopted as solvency capital required according to Solvency II regime.

#### 402 4.1 Earthquake Risk Assessment Results

403 Figure 7 shows the spatial distribution of seismic AAL for all residential building types in Iran, aggregated at the  
404 county level. Few studies exist on seismic risk topic for Iran at a national level e.g., (Ghafory-Ashtiany & Nasseradi,  
405 2012), and (Motamed, et al., 2019) which were previously done by authors of this study and are thus considered  
406 biased to be used to validate the risk results. Therefore, a risk component validation method is followed to control  
407 the sensibility of the results, in which it is tried to validate the risk distribution and intensity based on the values in  
408 the exposure, hazard, and vulnerability models used. As observed, almost all parts of the country are exposed to  
409 medium and high levels of seismic risk, except for sparsely populated areas of central deserts and the northern  
410 coasts of the Oman Sea. There are also visible high-risk counties, especially around major cities of Tehran and Tabriz  
411 in northern and north-western Iran, as well as in other populated areas proximate to Mashhad (northeastern Iran),  
412 Esfahan (central Iran), and Ahvaz, Shiraz, and Kerman in southern parts of the country. This pattern seems to be in  
413 accordance with the distribution of different classes of buildings and their exposure to the seismic hazard (please  
414 see figures 2 and 5 and comparative vulnerability of main building types in Table 4); in areas with a concentration of  
415 buildings and very high level of earthquake hazard (such as in Tehran and Tabriz cities) the seismic risk is the highest.  
416 Similarly, we can witness a high potential of loss in the populated southern cities of Ahvaz, Shiraz, and Kerman, that  
417 are subject to medium to high seismicity. The city of Esfahan, despite being located in a low seismicity zone, also  
418 shows high seismic risk, most probably due to its very high building exposure (the second-highest exposure value  
419 after Tehran) and the prevalence of more vulnerable building classes of masonry and adobe (look at map 'a' and 'b'  
420 in Figure 5). In south-eastern Iran, where the province of Sistan and Baluchestan exists, a medium to rather high  
421 level of risk can be distinguished, mainly because of the high level of seismicity in southern parts of province,  
422 existence of extremely vulnerable types of buildings (e.g., adobe).

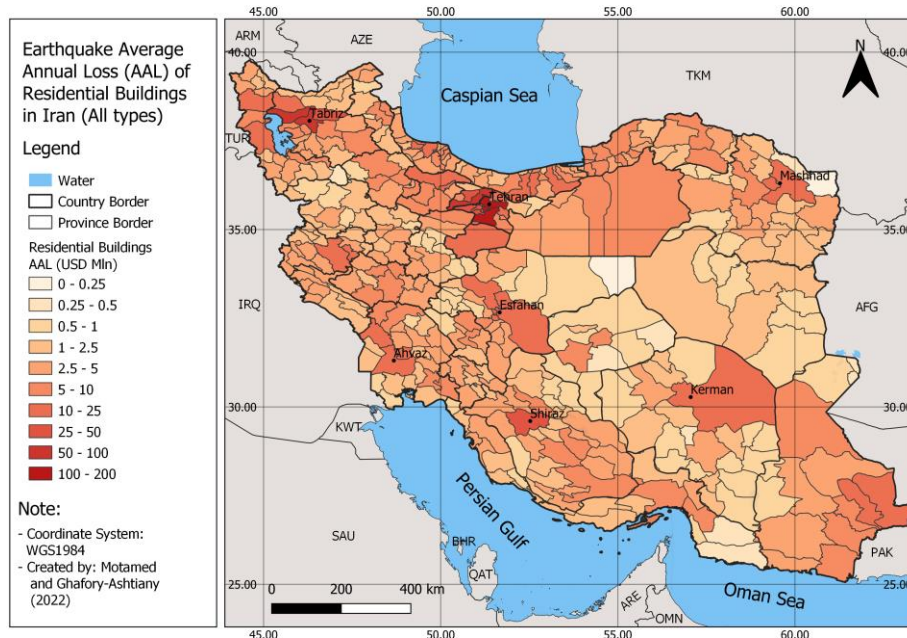

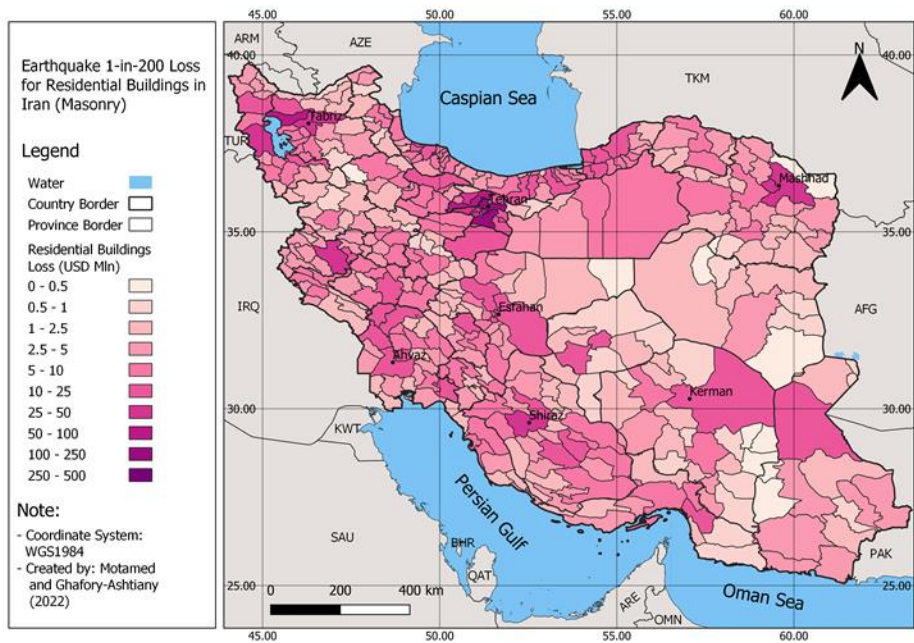

Figure 7 Earthquake Average Annual Loss (AAL) of residential buildings in Iran (million USD)

423 From what Figure 8 presented as the spatial pattern of 1-in-200-year losses of earthquakes in Iran, one could acquire  
 424 an idea of the level of earthquake insurance capital required by the Solvency II regime for different types of buildings  
 425 at the county level in Iran. Assuming a 100% insurance coverage for residential homes in Iran, the SCR or 1-in-200  
 426 loss for steel and reinforced concrete buildings would be the highest in Tehran, Tabriz, and to a lower extent in  
 427 Esfahan (and their surrounding counties). The situation is more homogenous for masonry structure (because of its  
 428 high prevalence and rather even distribution across the country), where significant seismic losses with 99.5%  
 429 confidence could be distinguished in almost all major cities in the country, namely Tehran, Tabriz, Mashhad, Esfahan,  
 430 Kermanshah, and Kerman. For adobe construction, again, a medium-to-high degree of losses could be expected in  
 431 many counties except for areas located in Khuzestan and Fars provinces in the southwest. The only observable  
 432 anomaly for 1-in-200 earthquake losses in adobe buildings is found in the country's most south-eastern counties in  
 433 Sistan and Baluchestan province, particularly along the border with Pakistan. This pattern could be first due to the  
 434 weighty number of absolutely vulnerable buildings made of adobe in these areas compared to other parts of the  
 435 country. The second reason would be the eminent seismicity of this region, which is influenced by both shallow  
 436 crustal and subduction seismic zones of Makran.

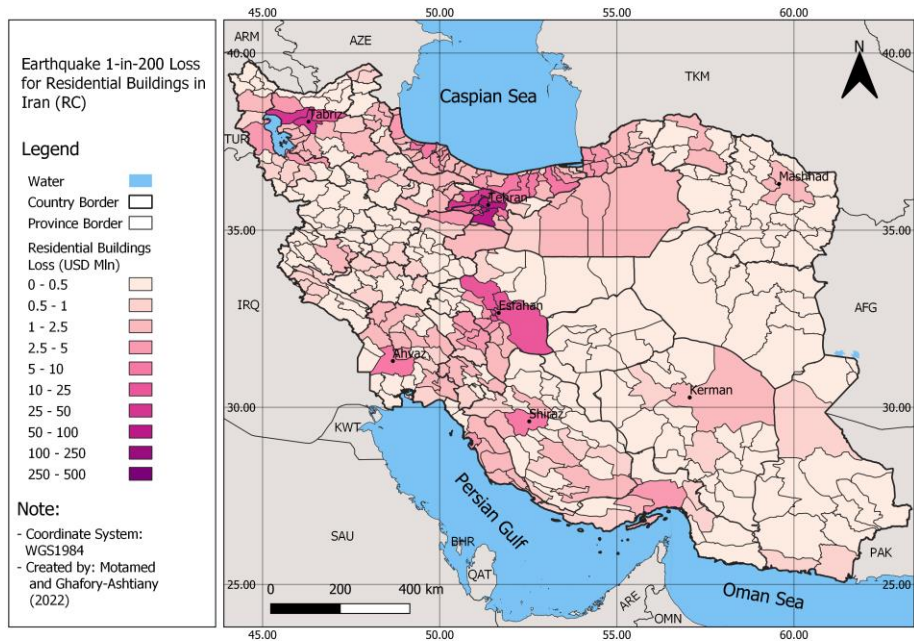

(a)

(b)

(c)

(d)

Figure 8: Earthquake 1-in-200 loss of residential buildings in Iran, adobe (a), masonry (b), steel (c), and concrete (d)

437 Table 5 presents the pure premium rate (AAL rate) calculated for the same cities previously selected in Table 1 of  
 438 Section 3. If we draw a comparison between these rates and those used currently by the market for pricing  
 439 earthquake insurance in Iran (Table 1), we notice a vast difference, implying a sizeable undervaluation of earthquake

440 risk in the Iranian insurance industry, including the insurers and supervising bodies like CII. Here, we used county-  
 441 level AAL rates as the representative of the modeled seismic risk of capital cities previously mentioned in Table 1.  
 442 This is because the current market rates are only retrievable at the city level from the Iranian insurance quote  
 443 aggregator websites.

444 This difference is more pronounced for cities with a higher level of seismicity, such as Tabriz where the modeled AAL  
 445 rate (8.65) is about eight times larger than the current market premium rate (1.1) for masonry buildings. Considering  
 446 that retrieved market premium rates are ‘technical premium’, the real discrepancy between risk-based and market  
 447 rates are event higher. For seismically calmer cities like Esfahan, the discrepancy becomes milder, reaching a ratio  
 448 factor of about 2 for reinforced concrete buildings.

**Table 5: Risk-based (modeled) earthquake pure premium rates (x 0.001) for different types of selected cities in Iran**

| Province        | County  | Capital city | Risk-based earthquake pure premium rates |       |          |
|-----------------|---------|--------------|--|-------|----------|
|                 |         |              | Masonry                                  | Steel | Concrete |
| Tehran          | Tehran  | Tehran       | 7.15                                     | 2.01  | 1.65     |
| East Azarbayjan | Tabriz  | Tabriz       | 8.68                                     | 3.73  | 3.03     |
| Esfahan         | Esfahan | Esfahan      | 1.07                                     | 0.45  | 0.20     |

449

450 **4.2 Calculation of Solvency Capital under Solvency II and Directive 69**

451 In this section, we utilize the modeled solvency capital rates, specifically the 1-in-200 loss rates, and the current  
 452 premium rates prevailing in the market (averaged across the market) to conduct a comparative analysis of the capital  
 453 requirements for earthquake risk in Iran. The assessment is based on two distinct methodologies specified by the  
 454 European Solvency II regime and the Iranian Directive 69. To highlight the difference between modeled (risk-based)  
 455 solvency figures and those calculated based on the earned premium which are, per se, acquired by underwriting  
 456 earthquake risks according to market premium rates, we use a hypothetical portfolio of risks in the five capital cities  
 457 we selected previously in section 3.1. As mentioned before, these cities have been selected because they represent  
 458 different seismic zones of Iran, namely Alborz (from northwest to north east including Tabriz and Tehran), Zagros  
 459 (west, south, and southeast, including Ahvaz and Kerman), and Central Iran (Esfahan). These cities also lie within  
 460 regions with different seismicity level, for example Tehran and Tabriz are highly seismic, Ahvaz and Kerman have  
 461 medium-to-high seismicity and Esfahan is located in a seismically calm area.

462 To illustrate the influence of building types on solvency capital, we examined three primary construction classes:  
 463 steel, reinforced concrete, and masonry. For all building classes, we assumed a replacement cost of USD 300 per  
 464 sqm and an average built area of 100 sqm per housing unit, consistent with the parameters used in the exposure  
 465 model. Additionally, we presumed an equal number of dwellings (100 dwellings for each construction type in each  
 466 city) within the hypothetical portfolio. Using the city- and building type-specific solvency capital rates, we calculated  
 467 the Solvency Capital Requirement (SCR) by multiplying the exposure values for each construction type by the  
 468 corresponding SCR rates. Subsequently, the city-level SCRs needed to be aggregated to the portfolio level. In the  
 469 Solvency II methodology, unlike Directive 69, which simply sums up city-level values to compute the portfolio-level

470 SCR, a geography-based correlation matrix is utilized to aggregate results. Therefore, we initially developed a  
 471 correlation matrix for the selected five cities.

472 Following a methodology akin to that outlined in Annex IV of Directive (2009) and CEIOPS (2010), we established five  
 473 province-level and one portfolio-level correlation matrices for the provinces hosting the pilot cities. The values within  
 474 these correlation matrices were determined based on the proximity of administrative divisions, considering the  
 475 relative positioning of counties within each province and the proximity of provinces. It was assumed that each county  
 476 exhibits 100% correlation with itself. Similarly, each province is considered fully correlated with itself, reflected by a  
 477 correlation value of 1.0. Furthermore, a 50% correlation was assumed between each county and its neighboring  
 478 county. For provinces, a 25% correlation was assumed between proximate provinces, accounting for the larger  
 479 dimensions of provinces compared to counties. As an illustrative example, Figure A1 and Table A2 in the Appendix  
 480 depict the configuration of counties in Tehran province and its corresponding earthquake risk correlation matrix,  
 481 providing a visual representation of the methodology applied.

482 Table 6 shows the results of solvency capital calculation based on the two solvency regimes at the county, province  
 483 and portfolio levels for the hypothetical portfolio of risks.

484

485

Table 6: Earthquake risk solvency capital rates based on the methodologies suggested by the Iranian Directive 69 (D-69)  
 and Solvency II (S-II)

| Level     |         | Exposure<br>(USD million) |    |    | D-69 solvency capital<br>rates<br>(x 0.001) |      |      | S-II solvency capital<br>rates<br>(x 0.001) |      |      | D-69 solvency<br>capital (USD) | S-II solvency<br>capital (USD) |
|-----------|---------|---------------------------|----|----|---|------|------|---|------|------|--------------------------------|--------------------------------|
|           |         | M                         | S  | RC | M   | S    | RC   | M   | S    | RC   |                                |                                |
| Location  | Tehran  | 30                        | 30 | 30 | 0.64  | 0.29 | 0.29 | 17.00                                       | 4.76 | 3.89 | 36,540                         | 769,500                        |
|           | Tabriz  | 30                        | 30 | 30 | 0.64  | 0.29 | 0.29 | 17.25                                       | 8.65 | 6.00 | 36,366                         | 957,000                        |
|           | Esfahan | 30                        | 30 | 30 | 0.45  | 0.19 | 0.19 | 3.49  | 1.91 | 1.02 | 24,882                         | 192,600                        |
|           | Kerman  | 30                        | 30 | 30 | 0.64  | 0.21 | 0.21 | 7.44  | 2.74 | 2.42 | 31,842                         | 378,000                        |
|           | Ahvaz   | 30                        | 30 | 30 | 0.45  | 0.19 | 0.19 | 6.02  | 2.15 | 2.67 | 24,882                         | 325,200                        |
| Portfolio |         |                           |    |    |   |      |      |   |      |      | 154,512                        | 1,339,296                      |

486

487 As illustrated in the table, there's an approximately tenfold difference in the solvency capital requirement when  
 488 calculated using the approach specified by Directive 69 compared to the European Solvency II for the same residential  
 489 dwelling portfolio in the pilot cities. Two key factors contribute to this notable gap in required capital charges. Firstly,  
 490 the variance in catastrophe capital rates between Directive 69 and the Solvency II system plays a significant role. The  
 491 second contributing factor, albeit with a minor impact, is the dissimilarity in aggregation methods employed by each  
 492 methodology. In the Iranian approach, where portfolio capital is determined by summing up county-level figures, the  
 493 mitigating effect of geographical diversification is simply disregarded, leading to even higher results. According to the  
 494 data presented in Table 5, the Solvency II risk-based rates are roughly twenty times greater than the Directive 69  
 495 capital rates. As mentioned, this disparity is somewhat mitigated when aggregating the solvency capital at the  
 496 portfolio level. The ultimate catastrophe capitals at the portfolio level for the Iranian and European systems are  
 497 reported as USD 154,512 and USD 1,339,296, respectively.

499 The findings from the analysis indicate that the constant-factor approach utilized by the Central Insurance of Iran  
500 (CII) for calculating solvency capital related to earthquake risks significantly underestimates the risk compared to the  
501 methodology recommended by the Solvency II regime. This discrepancy raises concerns about the capacity of Iranian  
502 insurers and reinsurers to withstand catastrophic shocks stemming from medium to significant earthquake events  
503 in major cities across Iran. It is worth noting that, despite the low insurance penetration rate in Iran and the absence  
504 of medium to large events in main cities, there have been no recorded instances of catastrophe-related insolvency  
505 in the country. However, persisting with the current approach may jeopardize the stability of the insurance market  
506 in Iran, potentially giving rise to financial and social challenges in the event of future disasters.

507 Moreover, following the establishment of the Iran Building Catastrophe Insurance Pool (IBCIP), which provides  
508 primary insurance coverage for all residential buildings in the country, a substantial business opportunity arises for  
509 local insurance companies to address the gap between the partial coverage offered by IBCIP and the total insurable  
510 sum. However, if these insurance firms persist in utilizing the existing premium rates in this scenario, a significant  
511 accumulation of risk may occur over time due to the disparity between the actual risk and the written premium. This  
512 poses a considerable challenge, as the solvency capital held by these entities might be inadequate to cover losses  
513 resulting from medium-to-large seismic events in urban settlements, potentially leading to the insolvency of Iranian  
514 insurers. Additionally, given that a majority of domestic insurance firms are reinsured internally due to financial  
515 sanctions on Iran, the solvency issues of insurers could potentially have repercussions on other financial institutions.  
516 To break this cycle of catastrophe risk accumulation, it is advisable for the Iranian insurance regulator to transition  
517 from the current catastrophe pricing practice to a risk-based pricing system, incorporating scientifically-approved  
518 catastrophe modeling techniques.

519 Another consideration which is relevant to the topic of insurance solvency is the public-private collaboration for  
520 adopting and implementing new measures like the risk-based catastrophe solvency requirement. As the first step,  
521 governmental bodies and insurers can initiate educational programs to raise awareness about catastrophe  
522 modeling's significance in assessing natural hazards risk. Forming alliances between international institutions and  
523 local insurers is beneficial for knowledge exchange, especially amid current financial sanctions. Moreover, the  
524 government can incentivize insurers to integrate catastrophe modeling into risk assessments before enforcing  
525 capital mandates. This involves offering tax benefits or reduced regulatory burdens, prompting insurers to embrace  
526 advanced risk evaluation tools. These proactive steps aim to fortify the Iranian insurance market, preventing  
527 undervaluation, and enhancing resilience through modern practices.

528 It is important to note that due to the lack of frequent seismic losses, validation of an earthquake risk model is  
529 challenging because the average of past losses is not a correct representative of seismic risk in a given area.  
530 Depending on the utilized resolution, hazard model, vulnerability curves, exposure data, and loss calculation  
531 method, different risk results can be generated by various models. This is something accepted in the insurance  
532 market. When comparing the results to other studies, special attention should be given to possible differences in  
533 input data and assumptions. For example, when we compare the ratio of AAL in (Kohrangi , et al., 2021) which  
534 presents the results of a seismic risk assessment for the city of Esfahan with ours, we should notice the difference in  
535 the vulnerability curves, vintage of exposure data, and the most importantly the resolutions of the analysis (county-  
536 level in our study versus city-level in theirs). That said, our AAL ratio of 0.55 per thousand for the county of Esfahan  
537 (which includes other cities with lower seismicity level in addition to the city of Esfahan) can be comparable with  
538 AAL ration of 1.9 calculated for the city of Esfahan in that study. Undoubtedly, an enhancement in the quality of  
539 input data and assumptions will enable a more precise assessment of the seismic risk associated with Iranian

540 buildings. This, in turn, would contribute to a more accurate evaluation of the prevailing insurance underwriting and  
541 pricing practices.

## 542 6 Conclusion

543 A numerical analysis was carried out in this paper to compare the earthquake catastrophe capital required by the  
544 European Solvency II and Directive 69 of the Central Insurance of Iran. Based on the literature reviewed, in the  
545 Iranian system, a constant factor is used to compute catastrophe charges based on each policy's earned premium  
546 and incurred losses. These earned earthquake insurance premiums are the result of an underwriting practice that  
547 uses a market-agreed rating schemes which seems to be not a proper representative of the existing seismic risk in  
548 the country. On the other hand, the Solvency II Directive requires a risk modeling-based capital calculation approach  
549 to compute the necessary catastrophe charge. In addition to the difference in the calculation of solvency capital  
550 rates, there is also a discrepancy between the two methodologies in risk aggregation: while the Iranian directive  
551 simply sums up the required capital charges at the city-level to calculate the portfolio-level figure, the European  
552 regime considers the diversification impact by making use of correlation matrices. To be able to implement Solvency  
553 II approach in calculating the risk-based solvency capital, a seismic risk model has been developed by adopting  
554 Earthquake Model of Middle East (EMME) seismicity model (Şeşetyan, et al., 2018), creating an exposure model for  
555 Iranian residential buildings based on the newest census data, using an earthquake vulnerability model for Iranian  
556 buildings (Mansouri & Amini-Hosseini, 2013), and combining in GEM's OpenQuake hazard and risk assessment  
557 engine. Average Annual Loss (AAL) and 1-in-200 EP values have been calculated for four main types of Iranian  
558 buildings at 30-second arc grid granularity.

559 The initial segment of the numerical findings was presented as the Average Annual Loss (AAL) and Exceedance  
560 Probability (EP) figures at the county level, achieved by aggregating the OpenQuake risk output tables for four  
561 distinct construction types. A comparison between these values and the AAL rates currently employed in the Iranian  
562 insurance market reveals a noticeable undervaluation of seismic risk, ranging from 1/2 to 1/8, depending on the risk  
563 location and construction type. Furthermore, to comprehend the implications of this dissonance between risk  
564 modeling-based and market-agreed rates, we computed the earthquake capital requirement for a hypothetical  
565 portfolio of residential dwellings in five Iranian cities situated in different seismotectonic zones. This calculation was  
566 conducted using the methodologies specified by Solvency II and the instructions provided by Directive 69 of the  
567 Iranian Central Insurance. The results demonstrate a significant 20-fold underestimation of earthquake solvency  
568 capital in the Iranian Directive 69 system compared to Solvency II. This undervaluation of earthquake risk poses a  
569 substantial risk of accumulating undue exposure for the Iranian insurance market. In the event of medium-to-large  
570 urban earthquakes, it could potentially lead to the insolvency of insurance undertakings due to the inadequacy of  
571 reserved catastrophe capital. We believe that this study is a unique and valuable in its kind for Iran and it could  
572 originate serious discussions and challenges for the bettering of the relevant sectors. It is worthwhile to mention  
573 that the earthquake solvency capital is a function of earthquake risk and risk appetite of the market. Here, we  
574 assumed a similar risk appetite between the Iranian insurance market and the European union. Although the average  
575 GDP per capita in the EU region is about 10 times Iran's, we are convinced that the earthquake capital requirement  
576 should follow the risk profile of the country and the sum insured. Given the significant impact of input data and  
577 models on the results of catastrophe modeling, it is crucial to acknowledge that a different risk perception may  
578 emerge if the same process is repeated using more recent exposure data or improved seismic hazard and  
579 vulnerability models, which may become available in the future.

580 In the end, the authors of this paper highly advocate for ongoing research focusing on various components of risk,  
581 specifically hazard, exposure, and vulnerability. Additionally, the introduction of more state-of-the-art earthquake

582 models is encouraged to foster a more comprehensive and accurate seismic risk assessment for the Iranian insurance  
 583 market. Moreover, although the subject of the paper is not directly related to parametric insurance, the seismic risk  
 584 model developed can be used to design a parametric product for earthquake, perhaps something useful for the  
 585 public natural hazard insurance fund in Iran.

586 7 Appendix

587 *Table A1: Riskiness of different construction types in Iran (Ghafory-Ashtiany, 1991)*

| Type | Building Typology  | Level of Earthquake Hazard |     |     |     |     |
|------|--|----------------------------|-----|-----|-----|-----|
|      |  | 1                          | 2   | 3   | 4   | 5   |
| 1    | Adobe and Traditional                                    | 1.0                        | 1.1 | 1.2 | 1.5 | 1.8 |
| 2    | Confined Masonry   | 0.8                        | 0.9 | 1.0 | 1.4 | 1.6 |
| 3    | Pre-code Steel Structure                                 | 0.6                        | 0.7 | 0.8 | 1.1 | 1.4 |
| 4    | Pre-code Reinforced Concrete                             | 0.4                        | 0.5 | 0.6 | 0.8 | 1.0 |
| 5    | Code Based Buildings Design and Construction (Post 1991) | 0.2                        | 0.3 | 0.4 | 0.6 | 0.8 |

588 Note: Hazard levels are based on zones defined in 'Iranian Code of Practice for Seismic Resistant Design of  
 589 Buildings - Code 2800' as 1: no, 2: low (0.2g), 3: moderate (0.25g), 4: high (0.3g), 5: very high (0.35g).

594 **8 Data Availability**

595 Data used in this research are the intellectual property of Iran National Science Foundation who funded the study  
596 and cannot shared by the authors.

597 **9 Authors Contribution**

598 In the preparation of this report, Prof. Mohsen Ghafory-Ashtiany has planned the research project and contributed  
599 to the content of different chapters mainly in the earthquake hazard and risk assessment and modeling and review  
600 and validation of results. Dr. Hooman Motamed has been mainly responsible for authoring the insurance regulation  
601 content and numerical analysis. Both authors have equally edited the final manuscript.

602 **10 Competing Interests**

603 The contact author has declared that none of the authors has any competing interests.

604 **11 Acknowledgement**

605 The authors would like to express their gratitude to Iran National Science Foundation for the financial support they  
606 provided for conducting this research work under the research project number 94811162.
